## DECLARATION

I declare that this is my own work and this thesis/dissertation does not incorporate without acknowledgement any material previously submitted for a Degree or Diploma in any other University or institute of higher learning and to the best of my knowledge and belief it does not contain any material previously published or written by another person except where the acknowledgement is made in the text.

Also, I hereby grant to University of Moratuwa the non-exclusive right to reproduce and distribute my thesis/dissertation, in whole or in part in print, electronic or other medium. I retain the right to use this content in whole or part in future works (such as articles or books).

Signature:  University of Moratuwa, Sri Lanka. Date:

## ACKNOWLEDGEMENTS

During this project, I had to put huge effort to touch the end. Some moments my feeling came closer to relinquish project due to busyness of my office duties. It will be an impossible attempt if there was not a grate support from many of individuals and organisations. I would like to grant my frank thanks to all of them.

Department of Mechanical Engineering, University of Moratuwa is especially appreciated regarding giving this opportunity to start Master of Engineering course. 300MW Norochcholai coal power plant and 600MW Norochcholai coal power project (Phase-II), Ceylon Electricity Board are reminded in deep heart regarding the providing assistances to conduct this research study.

Also I would like to grant my special gratitude to Dr. (Mrs.) M. M. I. D. Manthilake person who supervised and guided me. Furthermore I would like to express my thanks to Dr. Himan Punchihewa, M.Eng course coordinator of Energy Technology who gave respectable guides to complete this thesis. I would like to take this opportunity to extend my sincere thanks to all Engineers in CEB project staff and all nonacademic staff in Mechanical engineering department in University of Moratuwa.

I would also like to acknowledge with much appreciation the support and continuous encouragement and patience given by my family members during the period. My thanks and appreciations also go to my colleagues of M.Eng course 11th intake and people who have willingly helped me out with their abilities.

## ABSTRACT

Coal fired power plants are one of the main contributors in power generation in the world and it is nearly 40% of global power generation. When considering power generation in Sri Lanka, Puttalam Coal Power Plant is the largest and one and only coal fired power plant. Presently 900 MW is produced by three units of this power plant.

Coal fired power plants consume a considerable amount of energy as the home load. For example, many auxiliary systems such as pumping, cooling, coal handling, compressed air, HVAC and lighting. In the coal fired power plants in Sri Lanka, they account for 90 MW, which results in the supply of only 810 MW to the grid out of the produced 900 MW. The majority of auxiliary systems consist of electric motors as prime movers for pumps, compressors, conveyor belts and coal mills. The electricity generator is coupled with a steam turbine that uses the generated steam in the boilers. This system needs prime movers and that consumes the most amount of electricity, which is generated.

By reducing the home load in an efficient and a strategic manner, the power plant efficiency could be increased and more power can be supplied to the grid. However, the implementation of these changes for a power plant, which has already been constructed and operational, is difficult. Although it is a difficult attempt, it is worthwhile to explore the possibility to implement changes in the existing coal power plants. It could potentially yield positive results and incur savings.

This study has looked into ways to minimise the home load and propose alternative renewable energy options for the coal power plants. The research goes on to develop a method to recommend alternative energy options to address the home load needs of coal power plants. In order to evaluate this method, it has been applied to the Norochcholai power plant and to recommend the most suitable energy option to account for the home load. The results suggest that the developed method provides guidance to practitioners to decide the energy efficiency and renewable energy options to address the home load of coal fired power plants. It is suggested to further develop this method as a computer based software program in the future.

## CHAPTER 1 - INTRODUCTION

Electricity power generation is one of most popular and important topic which is being discussed in the present world. When considering the electric power generation, various technologies have been used for it. As examples, hydro power, petroleum based power sources, coal power and nuclear power generation are major techniques related to the electric power generation. In addition, wind power, solar power, tidal wave and geothermal can be seen as minor techniques. Comparatively few advantages and disadvantages can be seen in the use of all these sources. For the selection and successful utilisation of a certain power source, the above mentioned advantages and disadvantages are the main key factors. Therefore in the power generation, cost of a source, availability and extractability of a source are very critical [1].

Among the above major technologies, coal based electric power generation is comparatively a less expensive source to produce power. When compared with hydro power generation, it could be more expensive. Higher number of availability index is inherited to coal than the hydro sources [1]. Coal electric power generation was started in about year 1880 and it has been continuously developed, and also successfully being used until today [2]. It is a strong evidence that shows how far the above factors are applied to coal power generation then to other sources. Therefore, a considerable percentage of world electricity power generation is done, based on coal power plants. It is nearly 40% of global power requirement [3] and it is nearly 985 GW [4]. Therefore whatever the disadvantages are, coal power plants have been utilised adding new technologies and features for a long time. In addition to currently operated coal power plants, large numbers of coal power plants are planned to be installed with new technologies.

The number of operating coal power plants in the present world are about 1220 [4] and over 1200 of plants are planned to be installed [5]. When considering the familiarity of coal electric power generation in Sri Lanka, it is a new experience. The first coal power plant with 300 MW capacity is currently operated at Norochcholai, Puttalam. Another two units with 600 MW total capacity were recently

commissioned and grid connected [6]. Meanwhile, an agreement has been signed for a coal power plant with 500 MW capacity at Sampoor, Tricomalee. A new proposal is also being discussed in Sri Lankan power generation sector regarding constructions of two coal power plants in Induruwa area and Hambantota [7]. Based on above facts, the main and strong role of electricity power generation in Sri Lanka as well as in world is done by coal power plants.

Electricity generation in a coal power plant is done based on the theories of thermodynamics and basic arrangement of equipment and operations which are almost similar for every coal power plant. Various power consuming equipment and components can be seen in such a power plant. Among these equipment, cranes for coal loading and reclaiming, conveyor belts for coal transferring, crushers for breaking coal into small particles, pulverisers for grinding coal into powder, various pumps for water pumping, different types fans for boiler air and flue gas system as well as compressors for compressed air and chill water system are involved with power generation[8]. These equipment are supportive for steam generation of boiler and power generation of turbine. These are called auxiliary equipment. Electrically driven motors are commonly used as their prime movers.

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
[www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

During the operation, considerable electric power is consumed by auxiliary equipment. This consumed power is called house load or home load. Required home load of the power plant is taken through its generator produced power output. Very rarely this home load requirement is fulfilled by outside power which is generated by another power plant. Therefore there is a great chance to save energy and money by reducing required home load for auxiliary equipment.

Although home load reduction is expected after introducing a new method, modification cost with respect to the expected power gain could be high. Therefore these facts should be studied deeply. To adjust the above idea for the existing coal power plant, identification of practicable alternative solutions and the ways of using mechanisms should be done.

## 1.1 Background

Electric power is produced by the turbine coupled electric generator based on the thermodynamic theories. This power output is called as plant generated power output. Certain fraction of plant generated power output is used as the home load of the power plant. In 300 MW Norochcholai coal power plant, nearly 30 MW power out of its generated power output is consumed as home load. Although its plant generated power output is 300 MW [8], grid feeding capacity is nearly 270 MW [8]. Large numbers of auxiliary systems and equipment contribute to this 30 MW home load in Norochcholai power plant.

Coal handling system has several unloading cranes, conveyer belts, coal crushers and pulverisers. This system consumes nearly 1.1 MW from home load. Boiler feed water system has several high capacity pumps such as condensate pumps, booster pumps and main boiler feed pump (BFPs). 2.24 MW, 1.2 MW and 9.6 MW power capacities are respectively consumed by these pumps. It nearly consumes 10.8 MW out of 30 MW plant home load [13].

Sea water pre-treatment plant, desalination plant, reverse osmosis plant and chlorination plant are the main water processing plants and a large number of different types of pumps are involved with these plants [8]. Nearly 1.8 MW power is consumed from home load by these auxiliaries [13]. Furthermore, condenser cooling system requires a water flow with 18 m<sup>3</sup>/s flow rate [8]. The required water flow for condenser cooling is supplied by two axial pumps with 3.2 MW capacity [13]. In the air and flue gas handling system, several forced draft (FD) and induced draft (ID) fans are used. 1.4 MW and 2.5 MW powers are respectively consumed by FD fans and ID fans in Norochcholai power plant [13]. A large number of compressors which are attached to the compressed air system and chill water systems consume about 1.75 MW auxiliary power from home load [13]. In addition, the large numbers of small auxiliary components contribute to the home load in Norochcholai coal power plant.

## 1.2 Motivation

The above discussed main auxiliary systems and their processes support to the functions of steam generation through the boiler and the correct operation of the turbine. Therefore all processes are essentially required and can't be omitted. During the generation of 300 MW power, it takes about 30 MW power as home load. It is 10% of plant generated power output. Even though 30 MW is shown as a small figure, its sensitivity is important when compared with the national power production of a developing country like Sri Lanka. If it is taken through the Sri Lankan national grid, that power is equivalent to half the power capacity of Canyon hydro power plant [15] or it is equivalent to power capacity of 5 or 6 mini hydro plants in Sri Lanka or power capacity of a wind farm with 20 wind towers [15]. Based on all the above facts and characteristics of the home load, its influence to grid power supply is proved without any doubt.

Zeroing the home load is impossible, because it is strongly related with main loop of plant power generation. Any attempt to reduce home load in an efficient and strategic manner is very important. For an example, 3% reduction of home load or reducing by 1 MW gives more benefits. If there is a way to operate the above auxiliary equipment by using alternative power source in a power plant instead of utilising home load through plant generator output, it may minimise the actual home load without interrupting the main loop of power plant. To make it as a valuable motivation, the problem is required to be identified well. It is also necessary to observe the technical and economical aspects of this problem.

## 1.3 Problem statement

As discussed earlier, home load is catered by the auxiliary power requirement of power plant. The portion of the home load for building lighting and electronic equipment such as computers and displays is very small. Therefore the influence to home load by lighting, computers and displays is negligible. A great portion of the home load is allocated for the main auxiliary systems. A particular auxiliary system could consist of a pump, compressor, fan, crane, conveyor belt, crusher or pulveriser. The common feature of all these auxiliary components is the utilisation of electric

motor as its prime mover. This means a great percentage of home load is consumed by electrically driven motors.

When considering the power consumption of auxiliary equipment in a coal power plant, pumps consume a considerable portion of home load. Applying this to the Norochcholai coal power plant, it is nearly 18.5 MW [13]. As a percentage, it is nearly 61.7% of plant house load. See Table 1.1 [13].

Table 1.1 : Home load contribution of auxiliaries in NCPP

| Type of equipment | Total power consumption(MW) | As a percentage of home load |
|-------------------|-----------------------------|------------------------------|
| Cranes            | 0.80                        | 02.67 %                      |
| Conveyor belts    | 1.05                        | 03.50 %                      |
| Coal crushers     | 1.00                        | 03.33 %                      |
| Pulverizers       | 1.35                        | 04.50 %                      |
| Pumps             | 18.50                       | 61.66 %                      |
| Fans              | 4.85                        | 16.17 %                      |
| Compressors       | 1.10                        | 03.67 %                      |

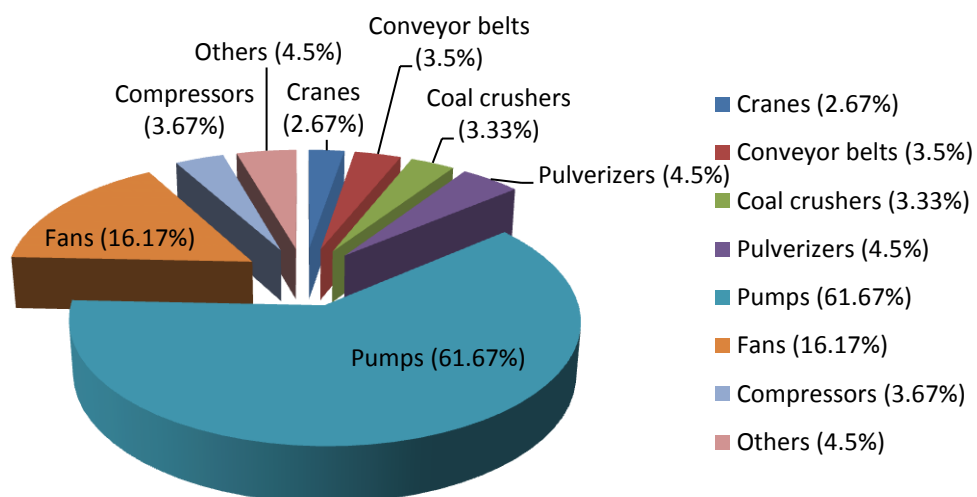

Figure 1.1 : Pie chart for power consumption of auxiliaries in NCPP

Based on the above observations, it is clear that the electric motors of the pumps in auxiliary systems strongly influence to the plant home load.

In considering the power consumption of pumps in a coal power plant, it can be clearly observed that the boiler feed pumps consume massive portion of home load. In applying this to the Norochcholai coal power plant, it is near 9.6 MW [13]. As a percentage, it is nearly 54.87% of load portion of the pumps. also it is nearly 32% of plant house load [13]. See Table 1.2.

Table 1.2 : Home load contribution of pumps in NCPP

| <b>Pump</b>                  | <b>Total power consumption (MW)</b> | <b>As a percentage of load of pumps</b> | <b>As a percentage of home load</b> |
|------------------------------|-------------------------------------|---|-------------------------------------|
| Makeup water transfer pump   | 0.10                                | 00.57 %                                 | 00.33 %                             |
| Condensate water pumps       | 0.50                                | 02.86 %                                 | 01.67 %                             |
| Booster pumps                | 0.85                                | 04.86 %                                 | 02.83 %                             |
| Main boiler feed water pumps | 9.60                                | 54.86 %                                 | 32.00 %                             |
| Condenser cooling pumps      | 2.80                                | 16.0 %                                  | 09.33 %                             |

| Pumps in pre-treatment plant | 0.45                                | 02.57 %                                 | 01.50 %                             |
| Pumps in desalination        | 0.75                                | 04.29 %                                 | 02.50 %                             |
| Pumps in RO plant            | 0.41                                | 02.34 %                                 | 01.37 %                             |
| Pumps in firefighting system | 0.58                                | 03.31 %                                 | 01.93 %                             |

Figure 1.2 : Pie chart for power consumption of pump in NCPP

Based on the above observations, it is very clear that the electric motors of the boiler feed pumps critically influence to the plant home load. Therefore the boiler feed pump is the most important contributor for home load. The criticalness of this contribution is intensified by nature of its operation pattern. In a coal power plant, some pumps are frequently operated. Some of them are used infrequently. When considering the BFPs, they continuously operate over the whole operation time of the power plant. It is clearly proved by the operation patterns of pumps which are summarised in Table 1.3 in applying this to Norochcholai power plant [16]. This continued operation of boiler feed pumps intensifies the influence on plant home load.

Table 1.3 : Pump grading base on influence to home load

| Rank | Pump                         | Power consumption (MW) | Contribution to home load | Operating frequency |
|------|------------------------------|------------------------|---------------------------|---------------------|
| 01   | Main boiler feed water pumps | 9.60                   | 32.00 %                   | Continuously        |
| 02   | Condenser cooling pumps      | 2.80                   | 09.33 %                   | Continuously        |

#### 1.4 Aim and objectives

- Aim of the research

A great portion of home load in a coal power plant is consumed by boiler feed pumps. It is a key player of the home load. When introducing an alternative solution to minimise the home load, boiler feed pumps are the most important equipment which takes priority. Also it is very difficult to introduce an alternative solution to the existing coal power plant, because the plant has been constructed and is being operated.

Also the aim is to develop a method to introduce site available alternative energy options for boiler feed pumps to minimise home load in coal power plants

- Key objectives of the research

1. Identify the most popular alternative energy option applicable to coal power plants.

2. Develop a method to introduce most feasible alternative energy option for boiler feed pumps instead of the existing electric motor which is critically contributed to plant home load.
3. Evaluate the developed method applicable to the Norochcholai coal power plant

- Other objectives

1. Identify the alternative power sources related to the coal power plants
2. Identify the ways which can be used to estimate availability and power potential of alternative power source.
3. Study the power extraction ways and transferring techniques related to the alternative power sources in coal power plants.
4. Study the losses, advantages and disadvantages when transferring power applicable to alternative power sources in coal power plant
5. Identify the steps which are used to estimate the cost of implementing for alternative power source.

## 1.5

### Outcomes

1. To develop a method to introduce site available alternative energy options for boiler feed pumps instead of its electric motor .
2. To decide on the most suitable alternative energy option applicable to the Norochcholai coal power plant. .
3. To evaluate the method applicable to the alternative energy sources in Norochcholai coal power plant.
4. To estimate the power gain in Norochcholai coal power plant after introducing suitable alternatives.
5. To calculate the annual power saving, annual financial serving, annual coal serving and payback period after applying method to Norochcholai coal power plant.
6. To estimate the coal saving for future

## **1.6 Methodology**

The method to study the relevant information related to the coal power plants and their alternative energy options, and to carry out a comprehensive literature review. Based on the extracted information through the literature review, a common method is developed to introduce most feasible alternative energy option for boiler feed pumps in coal power plants. The developed method is evaluated by studying cases for the selected few existing coal power plants. Through the case studies, results of method are justified. Outcomes are obtained based on above justifications.

## **1.7 Introduction to chapters**

The first chapter of this study describes the power generation of coal power plants and related home load. The main contributors and key contributor are also highlighted. Alternative energy options and required feasibility factors when introducing are discussed in chapter two. The ability to implement each of the alternatives is checked with information found in various research papers and publications. Chapter three develops a specific method to introduce the most feasible alternative energy option for coal power plants. Developed method in chapter three is evaluated in chapter four using case study related to the Norochcholai coal power plant. The specific results which is obtained through case study is generalised in chapter five. The results of the study are discussed in chapter six and the last chapter is dedicated to present the conclusion about the findings of this study and the recommendations.

## CHAPTER 2 - LITERATURE REVIEW

In order to study alternative energy options to minimise home load in coal power plants first and foremost coal fired power generation and characteristics of home load need to be reviewed. Then the method which can be used for their implementation must be studied. For this, many cases are required to be studied by using various sources such as research articles, technical papers, journals and books, although these cases may not be fully applicable to the coal power plants. However some points and information could be extracted by referring to these sources. In addition, the concepts and factors appropriate to coal power plants can be observed by studying other similar cases. The observed factors from these studies are needed to be reviewed in depth. The main points then must be divided into sub items and they should be discussed with relevance to the topic. Following this procedure will be the entrance to study the minimising losses of home load related to the boiler feed pumps in coal power plants.

### 2.1 Coal fired power generation and home load

Electricity power generation is one of the most popular and important topics which is being discussed in the present world. When considering the electric power generation, various technologies have been used for it. In addition to the main equipment, large numbers of auxiliary systems can be seen in a coal power plant. Major auxiliary systems in a coal fired power plant are as below [69].

- i. Coal handling system
- ii. Boiler feed water system
- iii. Raw water processing and condenser cooling system
- iv. Flue gas handling and treatment system
- v. Compressed air and chill water system

To operate these auxiliary equipment in the power plant, considerable electric power is consumed by relevant motors. This consumed power is called house load or home load. This home load for a particular coal fired power plant is taken as its generator produced power output or as generated power by another power plant [18]. During the generation of the above power, several losses are occurred. For example, if this

home load is taken through steam power plant, mechanical losses due to energy conservation in turbine, losses in generator, losses during the power distribution due to transformers and conductors could be seen. Therefore there is a great chance to save energy and money by reducing home load with alternative energy options in the power plant. On an average, the home load of a coal fired power plant is nearly 10% of plant generated power output [10]. If there is a possibility to minimise the home load by at least 1%, considerable power and money can be saved in a coal power plant.

Introducing a solution for a new power plant which has not been constructed is a little easier than introducing it for the existing power plant. When introducing a solution to the existing power plant, many design aspects of the power plant have to be considered. In order to apply the above idea for the existing coal power plants, identification of practicable alternative energy options and the method of using it must be reviewed.

## 2.2 Design modification aspects

Reviewing the design modification aspects is very important in such a study. Although it may not be exactly similar to this case, several studies have been done in different industries to achieve similar objectives. According to several studies which have been published in many articles, it is imperative that observation and identification of all the alternative energy sources applicable to the location must be taken into consideration before implementing them [86, 87]. Sometimes, observation on alternative energy sources is done separately in the first stage. Then identification of practicable alternatives is done in the second stage [86]. In some cases, both observations and identifications on alternative sources are done in the same stage [87]. In addition to the two aspects, it is required to notify the main alternatives which are involved with the considered site. When compared with the first two aspects, this is not an imperative requirement. Sometimes it will be automatically notified, based on the levels which are going to be observed and identified as alternative sources [86, 87]. The aspect of level of design modification on existing

structures is decided by selected alternative power source and its power transferring easiness [88].

When implementing alternative energy sources for existing systems in an industry, required design modification on existing structures is another important aspect [88]. The availability of the alternative sources applicable to the considered industry and its time of operation are critical aspects of design modifications [88]. Further it is highlighted to check the cost involvement when implementing the alternatives, because this aspect will decide the economic feasibility of the implementation [88]. These economic aspects are checked in the last stages [86, 88]. Additionally the availability of alternatives and the implementation cost for each alternative should be separately analysed [88].

There are different opinions on the level of design modifications and the cost of implementations. In addition to the above mentioned design modification aspects, match the site available power potential and the required potential when substituting the existing requirements of the industry [87, 88].

Although the above discussed design modification aspects are not fully matched with the situation of coal power plant, the used methods and concepts which have been expressed to select aspects can be applied to coal power generation industry with appropriate changes. Based on the above concepts, the following design modification aspects have to be studied in depth.

1. Identify all alternative energy option and the most popular alternatives applicable to coal power plants [86, 88].
2. Availability of alternative power source applicable to coal power plants [86, 88].
3. Required level of design changes on the existing power plant [86, 87].
4. Power transferring easiness of each alternative power sources, because level of design modification is governed by power transferring easiness of the alternative source [87, 88].
5. Power potential of alternative sources applicable to the power plant [86, 87, 88].

6. Power extraction method, transferring techniques and their losses related to the alternative power source [88].
7. Implementation cost related to the each alternative power source in power plant [86, 88].

### **2.3 Alternative power sources**

There are two types of alternative power sources which are associated with coal power plants in the world. The alternative power sources are dependent on design parameters of the power plant and geographical location of the plant. Among these types, in-plant alternative sources are decided by design parameters of the power plant. Renewable alternative sources are decided by geographical localisation of the power plant [70].

#### **2.3.1 In-plant alternative power sources**

Several in-plant alternative energy options which are associated with thermal power plant have been listed in technical papers [71, 72]. Based on the review of the above articles, in-plant alternative power sources in thermal power plants can be listed as follows.

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
www.lib.mrt.ac.lk

- i. Mechanical power sources
- ii. Superheated steam sources
- iii. Chemical power sources

#### **2.3.2 Renewable alternative power sources**

Many number of renewable energy sources are commonly associated with thermal power plants including coal power plants [73, 74]. These renewable alternative power sources which are associated with power plants are listed below.

- i. Wind power
- ii. Solar power
- iii. Geothermal energy
- iv. Hydroelectric power
- v. Hydrokinetic power (Sea wave/Tidal)

### 2.3.3 Main alternative sources in selected coal power plants

Mechanical power and steam sources are the most commonly available in-plant alternative sources in coal power plants. In addition to the above in-plant alternative power sources, wind power, solar power and sea wave energy are the most commonly available renewable alternatives applicable to the thermal power plants [75].

When studying the background of Norochcholai coal power plant in Sri Lanka, Qingshan coal power plant complex in China, Paiton coal power station in Indonesia, Kendal coal power Station in South Africa and Kahalgaon super thermal power station in India, the popularity of available alternatives can be checked. The study of the background of the above power plants is useful to confirm the previously expressed opinions.

Table 2.1 : Summary of main alternatives in some selected CPPs

| Power station                       | In-plant alternatives |       | Renewable alternatives |          |       |
|-------------------------------------|-----------------------|-------|------------------------|----------|-------|
|                                     | Mech. power           | Steam | Wind                   | Sea wave | Solar |
| Norochcholai coal power plant[16]   | ✓                     | ✓     | ✓                      | ✓        | ✓     |
| Qingshan coal power complex[37]     | ✓                     | ✓     | X                      | X        | ✓     |
| Paiton coal power station[77]       | ✓                     | ✓     | ✓                      | ✓        | ✓     |
| Kendal coal power Station[78]       | ✓                     | ✓     | ✓                      | X        | X     |
| Kahalgaon thermal power station[79] | ✓                     | ✓     | ✓                      | X        | ✓     |

Norochcholai power plant and Qingshan coal power complex have been constructed according to the design of Harbin Turbine Company (HTC) in China [16]. The design of the Paiton coal power station was done by Siemens in Germany [77]. Kendal coal power Station is represented by the designs and technology of Alstom Company in United Kingdom [78]. Kahalgaon thermal power station has been constructed on the designs of Shanghai Power Company in China [79]. These coal

power plants are located in different geographical regions. According to reviewed information in Table 2.1 and the expressed opinions in journal of PowerGen Africa-2015, mechanical power and steam source are almost applicable with all coal power plants as in-plant alternative power sources. Among the renewable alternative sources, wind energy, solar energy and sea wave energy are dominant.

## **2.4 Observations on main alternative sources**

As discussed in section 2.3, five main alternative energy sources can be commonly listed. For the successful study of these alternatives, it needs to observe separately their various features such as origination of the source, the available number of sources and common usage of the source applicable to the coal power plants [86].

### **2.4.1 Mechanical power sources**

A few mechanical power sources can be identified in all coal power plants which are operated worldwide. In such a power plant, mechanical power sources are used to rotate the main generator shaft. When considering a coal power plant, the required mechanical power is produced as a result of expansion of steam which is generated by boiler in high pressure and high temperature condition through a steam turbine. This mechanical power is transferred to the main generator and very rarely a small fraction of this power is used to operate an auxiliary generator [72]. When designing a boiler or a steam turbine in a coal power plant, gross power output of a main generator is focused. In addition, the equivalent steam capacity for mechanical torque power of turbine or steam generation capacity in boiler is always higher than the equivalent steam capacity at the requirement of the generator rated output. When Norochcholai coal power plant in Sri Lanka is taken as an example, the required turbine mechanical torque power and boiler steam generation for 300 MW rated power and the maximum ability of producing mechanical torque power in the turbine and boiler steam capacities are shown in Table 2.2 [16].

Table 2.2 : Equivalent torque capacity of the 300 MW NCPP

| Designed capacity | Boiler steam generation<br>(T/hrs) | Turbine mechanical<br>torque power (kNm) |
|-------------------|------------------------------------|--|
| @ Rated power     | 964                                | 1000                                     |
| @ BMCR            | 1025                               | 1065                                     |

By referring to the data in Table 2.2, a special point can be clearly observed. Some considerable excessive mechanical power is available in a coal power plant and this excessive power can be used as prime mover. This alternative power source is not dependent on geographical location of the power plant [72].

#### 2.4.2 Super-heated steam source

When considering the steam generation in a coal power plant, it is done in the boiler by transferring heat energy which is obtained due to combustion of coal. To increase the energy which is carried by steam entering the turbine and prevent cavitation on the turbine blades due to water droplets of steam, boiler generated steam is required to be super-heated [16]. For that saturated steam is circulated through super heater tube panel of the boiler prior to entering into turbine. Purity and the temperature of steam entering the turbine are increased by above process. Maximum steam generation capacity of the boiler is higher than the equivalent steam generation for plant rated power output [16]. This situation is common for all coal power plants. For example, generated steam flow rates in boiler and flow rates of the turbine entering steam in 300 MW Norochcholai coal power plant are shown in Table 2.3 [16].

There are some particular reasons to produce excessive steam in such a coal power plant. As mentioned earlier, to increase the efficiency of thermal cycle it needs to heat up the feeding water up to certain temperature before entering boiler. This process is called re-generation stage of boiler feed water [16]. For doing re-generation process, boiler feed water is circulated through several heat exchangers which are at different temperature and pressure. One purpose of the above mentioned excessive steam is utilisation as heating source of these heat exchangers. In addition,

many steam requirements can be seen in a coal power plant for auxiliary purposes [13]. Although this auxiliary steam component is taken through an auxiliary boiler in the start-up time, during plant normal operation it is taken as a fraction of the boiler excessive steam. Boiler soot blowing and coal mill firefighting are major usages of auxiliary component. In some specially designed power plants, boiler supplies huge excessive steam quantity to other industries which are located outside the power plant. For example, several boilers of Qingshan coal power plant in China supply steam for nearby steel manufacturing factory [37]. When considering the above facts, most of the coal power plants in the world generate considerable excessive steam quantity through the boiler than the requirement of turbine rated steam flow capacity. This excessive steam quantity of a boiler varies from 10% to 20% due to power plant design requirement [16]. Therefore the above mentioned ability of generating excessive super-heated steam in boilers can be seen as an available power source in a coal power plant. This power source does not depend on geographical location of the power plant.

Table 2.3 : Steam flow conditions in boiler and turbine, NCPP

| Operation condition | Boiler steam generation (T/hrs) | Steam flow rate through turbine (T/hrs) |
|---------------------|---------------------------------|---|
| THA*                | 911.69                          | 845.6                                   |
| TMCR**              | 964                             | 893                                     |
| BMCR***             | 1025                            | 947                                     |

\* Thermal Heat acceptance

\*\* Turbine Maximum Continuous Rate

\*\*\* Boiler Maximum Continuous Rate

### 2.4.3 Wind power sources

Wind power sources are different from mechanical power sources and super-heated power sources around a coal power plant. It is directly governed by geographical location of the power plant. For example, wind potential around a power plant depends on its environment. Although excellent wind potential can be seen around a power plant which is located inshore with good wind pattern, the same wind potential cannot be expected around off shore power plants because it is disturbed by forests, buildings and mountains. Further, the yearly time length of wind season is another critical factor for wind potential. Many of the inshore coal power plants such as Norochcholai, Sri Lanka have great wind potential. Estimated potential of wind in Norochcholai area is in between 500-600 W/m<sup>2</sup> [38]. Therefore, when considering alternative power sources around a coal power plant, significant involvement may be given by wind power sources.

### 2.4.4 Sea waves power sources

This alternative power source also depends on geographical location of the power plant. Although it does not have the ability to use this power source in offshore power plant, there can be great opportunity to use sea waves as alternative power source in power plant which is located onshore. Even though it is not attached with onshore coal power plants, there are several wave power plants and generate electric power by using sea waves. 22.5 MW Energias station in Portugal and Oregon wave power farm in Canada are good examples of this [39]. However this power potential is mainly governed by some factors such as depth of the shore, nature of the waves and annual seasonal conditions. Estimated sea wave power potential in shores near some coal power plants which have been proposed and constructed in Sri Lanka are shown in Table 2.4 [40, 54].

Table 2.4 : Potential of sea wave around coal power plants in Sri Lanka

| <b>Power plant</b>                      | <b>Depth of sea<br/>(m)</b> | <b>Power potential<br/>(kW/m)</b> | <b>Status</b> |
|---|-----------------------------|-----------------------------------|---------------|
| Norochcholai coal power plant           | 8-12                        | 20                                | Constructed   |
| Sampoor coal power project              | 24-28                       | 24                                | Proposed      |
| Southern coal power project-<br>Mawella | 15-18                       | 22                                | Proposed      |

#### 2.4.5 Solar energy

This alternative power source is not dependent on the location whether it is onshore or offshore. It is firmly linked with power plant position on the Earth [41]. Even though it is not jointly operated with a coal power plant, there are several solar energy power plants in the world. 1 MW Feranova CSP Plant in Turkey and 2 MW Keahole Solar Power station in USA are good examples of this [44]. The estimated solar power densities around some coal power plants which have been proposed and constructed in Sri Lanka are shown in Table 2.5 [43].

Table 2.5 : Density of solar energy around coal power plants in Sri Lanka

| <b>Power plant</b>                      | <b>Power density<br/>(<math>kWhm^{-2}/day</math>)</b> | <b>Status</b> |
|---|---|---------------|
| Norochcholai coal power plant- Puttalam | 5-5.5   | Constructed   |
| Sampoor coal power project – Tricomalee | 5-5.5   | Proposed      |
| Southern coal power project- Mawella    | 4.5-5   | Proposed      |

Estimated solar energy power densities around some coal power plants which are being operated in the world are noted in Table 2.6.

Table 2.6 : Density of solar energy around coal power plants in world context

| Power plant                                   | Power density <sup>[48]</sup><br>( $kWhm^{-2}/day$ ) | X, Y [37]              |
|---|--|------------------------|
| Amravati Thermal Power Station,<br>India [37] | 5-5.5  | 21°01'21"N,77°49'25"E  |
| Beijiang Power Station,<br>China [37]         | 4-4.5  | 39°13'08"N,117°55'50"E |
| Kendal Power Station,<br>South Africa [37]    | 5.25-5.75  | 26°05'24"S,28°58'17"E  |

## 2.5 Availability of alternative power sources

In attempting to energise the boiler feed pumps by using alternative energy option applicable to the power plant, some of them are common for all power plants and some alternatives are unique for considered power plants. Therefore it needs to individually observe their feasibility to use them as an alternative.

### 2.5.1 Availability of mechanical power sources

Mechanical power sources are one of the common alternative options which can be seen in any power plant in the world. Some parameters such as capacity of the source and availability of the source differ from plant to plant [16]. This mechanical power source in a power plant can be seen as the output torque of turbine shaft. These turbine systems are operated with some excessive mechanical power. Hence the ability of mechanical power extraction over full time of the turbine operation, availability of the power source is very high. The extractable power capacity is decided by design parameters of the power plant [16].

### 2.5.2 Availability of super-heated steam sources

Super-heated steam sources are another most common energy source which can be seen in all steam power plants including coal power plants. When considering the coal power plants, two types of superheated steam sources are involved [16].

- i. Super-heated steam through start-up boiler
- ii. Super-heated steam generation through main boiler

In a steam power plant, the leading steam production is done by main boiler for the purpose of electricity generation. In addition, one or two start-up boilers are used to fulfil unit start-up requirements [13]. Critical auxiliary steam requirements such as bottom heating of main boiler and de-aerator heating at initial start-up stage are accomplished by start-up boiler. After achieving stability of main boiler with certain steam flow rate, start-up boiler is shut down and requirements of auxiliary steam are shared by a fraction of main-steam. The auxiliary steam requirement is of a very small quantity, when compared with the main steam generation [13].

During the process of super-heated steam generation in main boiler, respectively feed water circulated through the economiser panels and the evaporative water walls. Finally it goes through the super heater panels. Conditioned super-heated steam enters into the high pressure turbine. Expanded steam through the HP turbine is called cold-reheated steam. Cold-reheated steam returns to boiler for further heat addition. This process is called as reheating part of the thermal cycle which increases the temperature and keeps the steam quality as recommended by the designer [16]. After energy addition in the boiler, it is called hot-reheated steam. Hot-reheated steam again enters into intermediate pressure turbine. Expanded steam through IP turbine enters into the one or two low pressure turbines. During the above process of super-heated steam generation and circulation through turbines, two main sources can be identified to extract excessive superheated steam [16].

- i. Through the outlet of start-up auxiliary boiler
- ii. Tapping through the extractions of regenerative heat exchangers

When considering the extracted steam through the first source point, its availability is very low, because this steam source is available only during unit starting time. The availability of second sources is of a comparatively high capacity, because once the boiler system is stabilised after the unit start-up, all tapping points are ready at any time to extract steam. In a coal power plant, several stages with various pressure and temperature conditions are involved to accomplish this regeneration part. Source details for steam extraction with reference to the Norochcholai coal power plant are shown in Table 2.7 [8].

Table 2.7 : Tapping points for regenerative heat exchangers for NCPP

| Steam Condition                        | Stage | Heat exchanger | Tapping Source       |
|--|-------|----------------|----------------------|
| Low Pressure<br>&<br>Low Temperature   | 1     | # LP 8         | Outlet of LP turbine |
|  | 2     | # LP 7         | Outlet of LP turbine |
|  | 3     | # LP 6         | Inlet of LP turbine  |
|  | 4     | # LP 5         | Inlet of LP turbine  |
| High Pressure<br>&<br>High Temperature | 5     | # HP 4         | Outlet of IP turbine |
|  | 6     | # HP 3         | Inlet of IP turbine  |
|  | 7     | # HP 2         | Cold Re-heater       |
|  | 8     | # HP 1         | Inlet of HP turbine  |

### 2.5.3 Availability of wind power

This is an alternative energy source that is dependent on geographical location of the plant and its availability is decided by many other parameters. As it is not fully available energy source over one whole year, continuous power supply cannot be guaranteed.

### 2.5.4 Availability of sea waves

According to the analysis of the wave energy resource at the European Marine Energy Centre, the amount of energy which is extracted through sea wave is decided by height of the waves [40]. The wave height is dependent on the seasonal wind pattern [47]. Therefore the monsoon pattern is a very important factor to calculate the availability of wave energy in a particular area [47].

### **2.5.5 Availability of solar energy**

Power plants which are located near the Equator have good solar energy intensity. The power plants which are far away from the Equator do not have considerable solar energy intensity, because this source is dependent on geographical location of the power plant [48]. Therefore the availability of the source is governed by seasonal patterns [48]. The solar power is only available during day time. When compared with the operation of the power plant, it operates both day and night. This issue is one of major limitations of solar power availability [44].

## **2.6 Power extraction methods and transferring techniques**

Different types of power extraction methods and transferring mechanisms can be seen in present technology. It is very important to study separately their features with relevant to the each of the sources.

### **2.6.1 Mechanical power extraction methods and transferring techniques**

Several power extraction methods and transferring techniques are used to extract and transmit power from such a mechanical power source. These methods are involved in different applications due to various reasons. Among these methods, mainly three ways of mechanical power extraction can be seen in the world power context [80].

- i. By coupled directly to driving shaft.
  - ii. Using gear mechanisms.
  - iii. Using belt or chain drives.
- Losses in mechanical power extractions and transferring

Direct coupling method is applied for extracting mechanical energy from high speed rotating shaft. Such a turbine rotor in a power plant is rotated at 3000 rpm. When using direct coupling method for high speed rotor, losses are low [80]. Instead of direct coupling method, gear mechanisms can be used to extract power. Formation of high level of noise and temperature on the system is an unavoidable drawback in this method [45]. Huge friction losses are involved with this due to metal to metal contact with gear teeth. Therefore the overall efficiency is considerably low in this method [45, 80]. In addition, belt driver and chain mechanisms are used to extract energy from rotating shaft [80]. Considerable energy losses occur as slip loss and friction

loss respectively. Formation of high level of noise and temperature can be observed when using the chain mechanism [45].

- Advantages and disadvantages of mechanical power extractions and transferring

The usage of direct coupling method is economical. According to the technical point of view, there is a possibility to transfer unnecessary vibration from newly attached equipment, because the relevant equipment is directly coupled with the main turbine. According to the installation manual of Harbin Turbine Company in China, the main turbine rotor is statically and dynamically balanced in factory before site installation [81]. Therefore the influence of unexpected vibration which is transferred from the newly linked equipment is not good for the main turbine and its life time. Easy maintenance, low level of fallibility and high level of reliability are other advantages.

Gear mechanisms are suitable for low speed rotors [80]. In economical aspect, initial installation cost as well as maintenance cost is comparatively high. Unwanted vibration from newly attached equipment can pass through the gear mechanisms. It needs several auxiliary systems such as lube oil and cooling system [45, 80]. This technique is not good for high speed applications. Even though the fallibility level is comparatively high, the newly attached equipments can be repaired in an emergency situation without shutting down the main steam turbine [45].

The usage of belt or chain drives are a low cost technique and the relevant technology is simple and common. The ability of maintenance is easy and maintenance cost is very low. Due to the using of belt and chain drives, influence of outside vibration to main turbine rotor is low in this technique [80]. However, high level of fallibility and low energy extraction efficiency are some disadvantages of these techniques. It is difficult to maintain constant speed in driven equipment due to belt slipping [45].

Table 2.8 : Summary of limitations for transferring mechanical power

| Mechanism                | Based on technical aspects  |   | Based on economic aspects  |  |

### 2.6.2 Steam extraction methods and transferring techniques

Four types of methods can be seen in the present applications to extract energy from steam source [81].

- i. Utilisation of steam turbine
- ii. Shell and tube heat exchangers
- iii. Mixed bed type heat exchangers
- iv. Metal to metal heat exchangers

The steam piping is used with steam turbine to transfer power. Combination of steam and water piping systems are used with the second and third extraction methods. Combination of steam piping and air duct systems are associated with the fourth method [81].

- Losses in steam extraction and transferring

Many different losses occur when using a steam turbine and steam piping. Pipe flow losses, component losses which are formed during the steam traveling from source to turbine, nozzle loss inside the turbine nozzle box and overall mechanical loss across the turbine can be identified as major losses [81].

In addition, many losses are involved when using the method of shell and tube heat exchangers. As usual, pipe and component losses are added during steam extraction from source to heat exchanger. Furthermore certain level of heat energy loss across the shell can happen although heat exchanger is fully insulated. When considering the mixed bed type heat exchanger, all of the above losses which are involved in shell and tube heat exchanger occur [46, 81].

In this method, huge amount of flashed steam is suddenly formed due to super-heated steam in high pressure and temperature directly mixing with water. This flashed steam accumulates in the heat exchanger. Therefore a certain amount of flashed steam is continuously removed in such a situation for safety purposes. Considerable energy loss occurs by removing flashed steam. Some kind of flashed steam recovering systems have been introduced for the present power plants. Therefore the losses due to flashed steam can be reduced up to a certain level [81].

Metal to metal heat exchanger technique is not commonly utilised in coal power plants. High significance level of loss can be seen due to steam losses when using such type heat exchangers with high pressure and high temperature super-heated steam [46, 81].

- Advantages and disadvantages of steam extraction and transferring

Even though the installation procedures of a steam turbine are a little complicated, using technology for turbine installation is well established in the world [46]. Presently, there is an ability to select and buy steam turbines in a wide capacity range as per the requirement. The efficiency of steam turbines is comparatively at a higher range [46]. Also the energy extraction rate is high. Its installation is not easy. During the operation, many operation parameters are needed to be controlled. Repairing and maintaining procedures are not simple. It needs well trained persons to operate and maintain them. Therefore cost for initial installation, operation and maintenance is considerably high [46, 81].

In the second and third methods, operation and maintenance cost is comparatively low although the initial installation cost is high. Few technical limitations can be seen in these methods. Energy extraction rate is comparatively low. Extracted energy by these methods is absorbed by water. Therefore it needs several complicated energy conversion steps to use it as a convenient power source. The overall efficiency goes down when using such complicated energy conversions [81].

When considering the fourth method, it is not a common technique in power plant industry although the metal to metal heat exchangers are applied as a useful way to extract energy from steam. The main advantage of this method is its ability to transfer the extracted energy into water as well as into air. Energy extraction rate and the efficiency are low. Also the installation cost, operation and maintenance cost are high [46, 81].

Table 2.9 : Summary of limitations for transferring steam

| Mechanism                              | Based on technical aspects  |   | Based on economic aspects  |  |

### 2.6.3 Wind energy extraction methods and transferring techniques

Different types of wind turbines in various capacities are used in wind energy field. Using a combination of mechanical linkages and a pump or using an electric motor are most common ways for transferring energy which is extracted by wind turbines. There are many practicable limitations when extracting energy through this method [82].

- Losses in wind energy extraction and transferring

Losses occur across the wind turbine are dominant. In addition, several sub losses are added when transferring mechanical energy from wind turbine output to equipment. Among the linking techniques which are applied to transfer energy, belt drives form losses due to slip and chain mechanism form friction loss. If the linked equipment is an electric generator, the overall loss through the generator is additionally added into the previously discussed losses [82].

- Advantages and disadvantages of wind energy extractions and transferring

Mechanically linked wind turbine systems are simple and the cost is low [45, 82]. Required maintenance is minimum and easy. The overall efficiency is very low when using mechanical linkages. Therefore, the efficiency can be increased by coupling an electric generator with wind turbine instead of mechanical linkages. Then again the high initial cost is applied due to complexity of generator installation. The level of reliability for the second method is higher than the first method [82].

Table 2.10. Summary of limitations for transferring wind energy

| Mechanism                        | Based on technical aspects   |  | Based on economic aspects  |   |
|----------------------------------|--|--|--|---|
|                                  | Advantages   | disadvantages  | Advantages   | disadvantages   |
| <b>With mechanical linkages</b>  | <ul style="list-style-type: none"> <li>• Common technology</li> <li>• Simple technology</li> <li>• Simple maintenance</li> </ul> | <ul style="list-style-type: none"> <li>• High Fallibility</li> <li>• Low energy extraction rate</li> </ul> | <ul style="list-style-type: none"> <li>• Low initial cost</li> <li>• Low Maintenance cost</li> </ul> |   |

#### 2.6.4 Sea wave energy extraction methods and transferring techniques

Two main ways are used to extract energy which is stored in sea waves [83].

- i. Transferring as mechanical energy
- ii. Transferring as electrical energy

In the first method, stored kinetic energy in sea wave is converted in to mechanical energy by using various mechanisms such as pendulum system, oscillating column of water system, power Buoy system and Salter's Duck system[47]. This mechanical energy is used to operate some reciprocating equipment like piston pumps. Belt or chain drives, long shaft system, rack and pinion mechanisms are used to transfer the mechanical energy to the relevant equipment after extracting from sea waves [83]. In the second method, the kinetic energy of sea waves is converted into mechanical energy in the same way as the first method. Then the converted mechanical energy is used to generate electricity through a generator. By using conductors, this electricity can be distributed to many of the equipment.

- Losses in wave energy extractions and transferring

In all techniques such as pendulum system, oscillating column of water system, power Buoy system and Salter's Duck system to extract sea wave energy, overall efficiency is at a very low level [47]. Huge friction loss is formed due to the involvement of some reciprocating parts such as pendulums, rack and pinions [47].

- Advantages and disadvantages of wave energy extractions and transferring

Wave energy offers renewability and its environmental friendliness. In addition, there are no considerable advantages in every mechanism which is involved in power extraction through sea waves, because the overall efficiency of all mechanisms is at a very low level. Installation and maintenance are quite difficult. Therefore the installation and maintenance cost in such a sea wave based power stations is rather high [47].

### 2.6.5 Solar energy extraction methods and transferring techniques

Solar power extractions are divided into two categories such as direct solar power extraction and indirect solar power extraction [84]. Using the direct solar power around a power plant is the most convenient way. Furthermore three main strategies to extract direct solar energy are used in solar power industry. The first strategy is the use of flat-plate collectors. It is a combination of arrays of solar panels arranged in a simple plane and commonly used. The second strategy is the use of focusing collectors. It uses flat-plate collectors with optical devices arranged to maximise the radiation falling on the focus of the collector. This methodology is used in a few scattered areas. The third strategy is the use of passive collectors. In this case, it absorbs radiation and converts it into heat naturally [84].

- Losses in solar energy extractions and transferring

Although the potential of solar energy is high, its rate of extraction is considerably very low. During the solar energy extraction by using the above methodologies, energy is wasted due to several factors such as unwanted heat conversion, photon pass through the solar cells and local recombination of newly created holes as well as electrons [48]. It nearly extracts one third of the total solar energy.

- Advantages and disadvantages of solar energy extractions and transferring

There are three main methodologies to extract solar energy. The flat-plate collector technique is of a low cost when compared with the other two techniques. Since these collectors extract energy individually, energy extracting rate is very low. When considering the focusing collector technique, the efficiency and energy extracting rate area little higher than the first method. Comparatively, using of passive collectors is the most efficient technique for extracting solar energy. However some common features such as low efficiency, low reliability, high initial cost, requirements of higher technology with reference to other alternatives can be identified as disadvantages in all techniques. The low operation and maintenance cost and environment friendliness can be seen as advantages of these techniques [48].

## **2.7 Power transferring easiness and required design changes**

When implementing a particular power source as the solution among the others, it needs to be done carefully, because it is going to implement changes on a power plant which has been constructed and is functioning now. Sometimes, it may be necessary to install new components or uninstall the existing components. In addition, laying new power cables, installing steam or water pipe lines and tapping or connecting pipe for existing systems may be expected. In an exceptional situation, it may have to change the civil structures such as construction of basements for new equipment or re-strengthen the basement.

### **2.7.1 Power transferring easiness**

There are three transmission ways to transmit energy from source to the place where the feed pumps are located [66]. If extracted output is electricity, it uses the various power conductors to transmit power. Also various types of mechanical linkages are used if the extracted output is mechanical energy. Steam or water pipes or air ducts are used to transmit energy if the extracted output is thermal energy[81].The requirement of design changes for the existing power plant can be easily identified through the power transmission way, because the required level of design changes are decided by these energy transmission ways. Extraction methods of the alternatives, extracted energy type of the alternatives and their transmission ways are summarised in Table 2.11 for easy reference.

Table 2.11 : Extracted energy outputs and transmission ways

| Power source              | Extraction method                                    | Type of extracted energy output | Energy transmission ways |
|---------------------------|--|---------------------------------|--------------------------|
| Mechanical power source   | Direct couplings                                     | Mechanical                      | mechanical linkage       |
|                           | Gear mechanisms                                      | Mechanical                      | mechanical linkage       |
|                           | Belt and Chain drives                                | Mechanical                      | mechanical linkage       |
| Superheated steam sources | Steam turbine  | Heat                            | Steam Pipe               |
|                           | Shell & tube Heat exchangers                         | Heat                            | Steam / water pipe       |
|                           | Mixed bed heat exchangers                            | Heat                            | Steam / water pipe       |
|                           | Metal to metal heat exchangers                       | Heat                            | Steam pipe/ Air duct     |
| Wind energy source        | Wind turbine + reciprocating equipments              | Mechanical                      | mechanical linkage       |
|                           | Wind turbine + electric generator                    | Electrical                      | Power conductors         |
| Sea wave energy           | All extraction techniques + reciprocating equipments | Mechanical                      | mechanical linkage       |
|                           | All extraction techniques + electric generator       | Electrical                      | Power conductors         |
| Solar energy              | All extraction methods                               | Electrical                      | Power conductors         |

Among the power transferring techniques, power transmission by using conductors in a power plant is the easiest way. Using steam piping is not easier than using power conductors. It is easier than power transferring by using mechanical linkages. Power transferring with mechanical linkages is very difficult in an existing power plant [85].

## 2.7.2 Required level of design changes

Although mechanical linkages can be commonly seen in the world, it includes lots of heavy gadgets such as gear mechanisms, belt drives, chain drives and rack and pinion method [80]. When installing these mechanical linkages, they require huge space. Therefore the utilisation of these types of energy transmissions with mechanical linkages requires many changes on the existing design.

Energy transmissions using steam or water pipe lines or air duct is more convenient than the first way. It also may require some changes on structures, existing pipe line with some design calculations [85].

Comparatively few changes on the existing design are required when energy transmission is done by using power conductors. Power cables can be laid underground or over cable tray. These modifications are easier than the installation of mechanical power transmission systems or piping system in a coal power plant which is already constructed [85].

Table 2.12 : Summary of required modifications on existing design

| Energy transmission ways                    | Nature of required modification | Examples for modifications  |
|---|---------------------------------|---|
| Using mechanical linkages                   | Need critical changes           | <ul style="list-style-type: none"> <li>• Need to be removed disturbances (equipment or structural) in between power source and BFP</li> <li>• New basements for equipments</li> <li>• Need protective enclosures for mechanical moving parts</li> </ul> |
| Using steam pipes / water pipes / air ducts | Need moderate changes           | <ul style="list-style-type: none"> <li>• Steam tapping connections are needed to be installed</li> <li>• Need new hangers and supports</li> <li>• Need thermal insulation for ducts</li> </ul>  |
| Using power conductors                      | Need minor changes              | <ul style="list-style-type: none"> <li>• Only new need cable trays of underground trenches</li> </ul>   |

## 2.8 Implementation cost of alternatives

Though any alternative may be selected as the solution, it needs to check its economic feasibility when analysing the overall feasibility. Therefore it is necessary to get an idea about the cost involvement when each alternative is used as solution. It can be separated into few sub cost components such as the cost for structural and design changes, the cost of new equipment and the installation cost. Based on the above cost separation, it is easy to study the cost involvement when substituting prime mechanism of the existing boiler feed pumps by each alternative. These studies are very important to decide many economical parameters such as initial cost of the project and the payback period.

Table 2.13 : Summary of implementing cost for mechanical energy source

| Method of extraction  | Cost for implementation of mechanical energy sources  |  |   |
|-----------------------|---|--|---|
|                       | Structural/Design changing cost   | New equipment cost   | Installation cost   |

## 2.9 Summary of the literature review

All possible alternative energy options applicable to coal power plants in the world have been identified in technical papers and engineering news journals. The different types of alternative energy sources are observed by applying them. Among all the possible alternative energy options applicable to the coal power plants, the most popular and commonly available options may be selected by studying the opinions which have been expressed in technical papers, books and engineering news journals. The correctness of the selected common energy options may be checked from the background of the five selected coal power plants where are located with different designs and different geographical regions.

Although it is not hundred percent equal to coal fired power industry similar researches and case studies which have been carried out in different industries in the world can be reviewed. The design modification aspects involved when selecting the most suitable and feasible alternative energy options for coal power generation should be studied. Based on the study, a conceptual framework can be designed and specific method can be developed. In order to compare and analyse the design modification aspects in qualitative and quantitative manner, the data and information gathered from various technical articles such as engineering news journals, text books, previous project proposals, operation and maintenance manuals of the existing power plants and World Wide Web can be used.

## CHAPTER 3 - DEVELOPMENT

As discussed in the literature review, a great portion of home load in a coal power plant is consumed by boiler feed pumps [8]. By introducing an alternative power solution for the existing boiler feed pumps in coal power plant which has been already constructed and operated, many positive outcomes can be obtained. For that, a specific method can be developed by considering all relevant background conditions and parameters in the power plant. Based on identification of literature review, two main in-plant power source and three main renewable energy sources are commonly applicable with all coal power plants [71, 72]. These alternative power sources are taken as variable inputs of the method. In addition, power demand of the boiler feed pumps motor is taken as an invariable input.

The availability of the power source, power transferring easiness, required design changes, power potential of the source and implementation costs are determined by relating them to the variable inputs. Equivalent power potential of alternatives to operate BFPs is determined in relation to the power demand of BFP motor. By matching power potential and equivalent power potential of the source, requirement for BFP power satisfaction is checked.

University of Moratuwa, Sri Lanka  
Electronic Theses & Dissertations  
[www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

To select key solutions, the analysis is carried out based on following feasibility factors.

- i. Availability of the alternative power source
- ii. Required level of design changes
- iii. Satisfaction of BFP power requirement
- iv. Implementation cost of the source

Then the developed method is evaluated by studying as a case for selected coal power plants. Outcomes of the method are obtained through the justification of selected solutions. The framework of the developed method is shown in Figure 3.1.

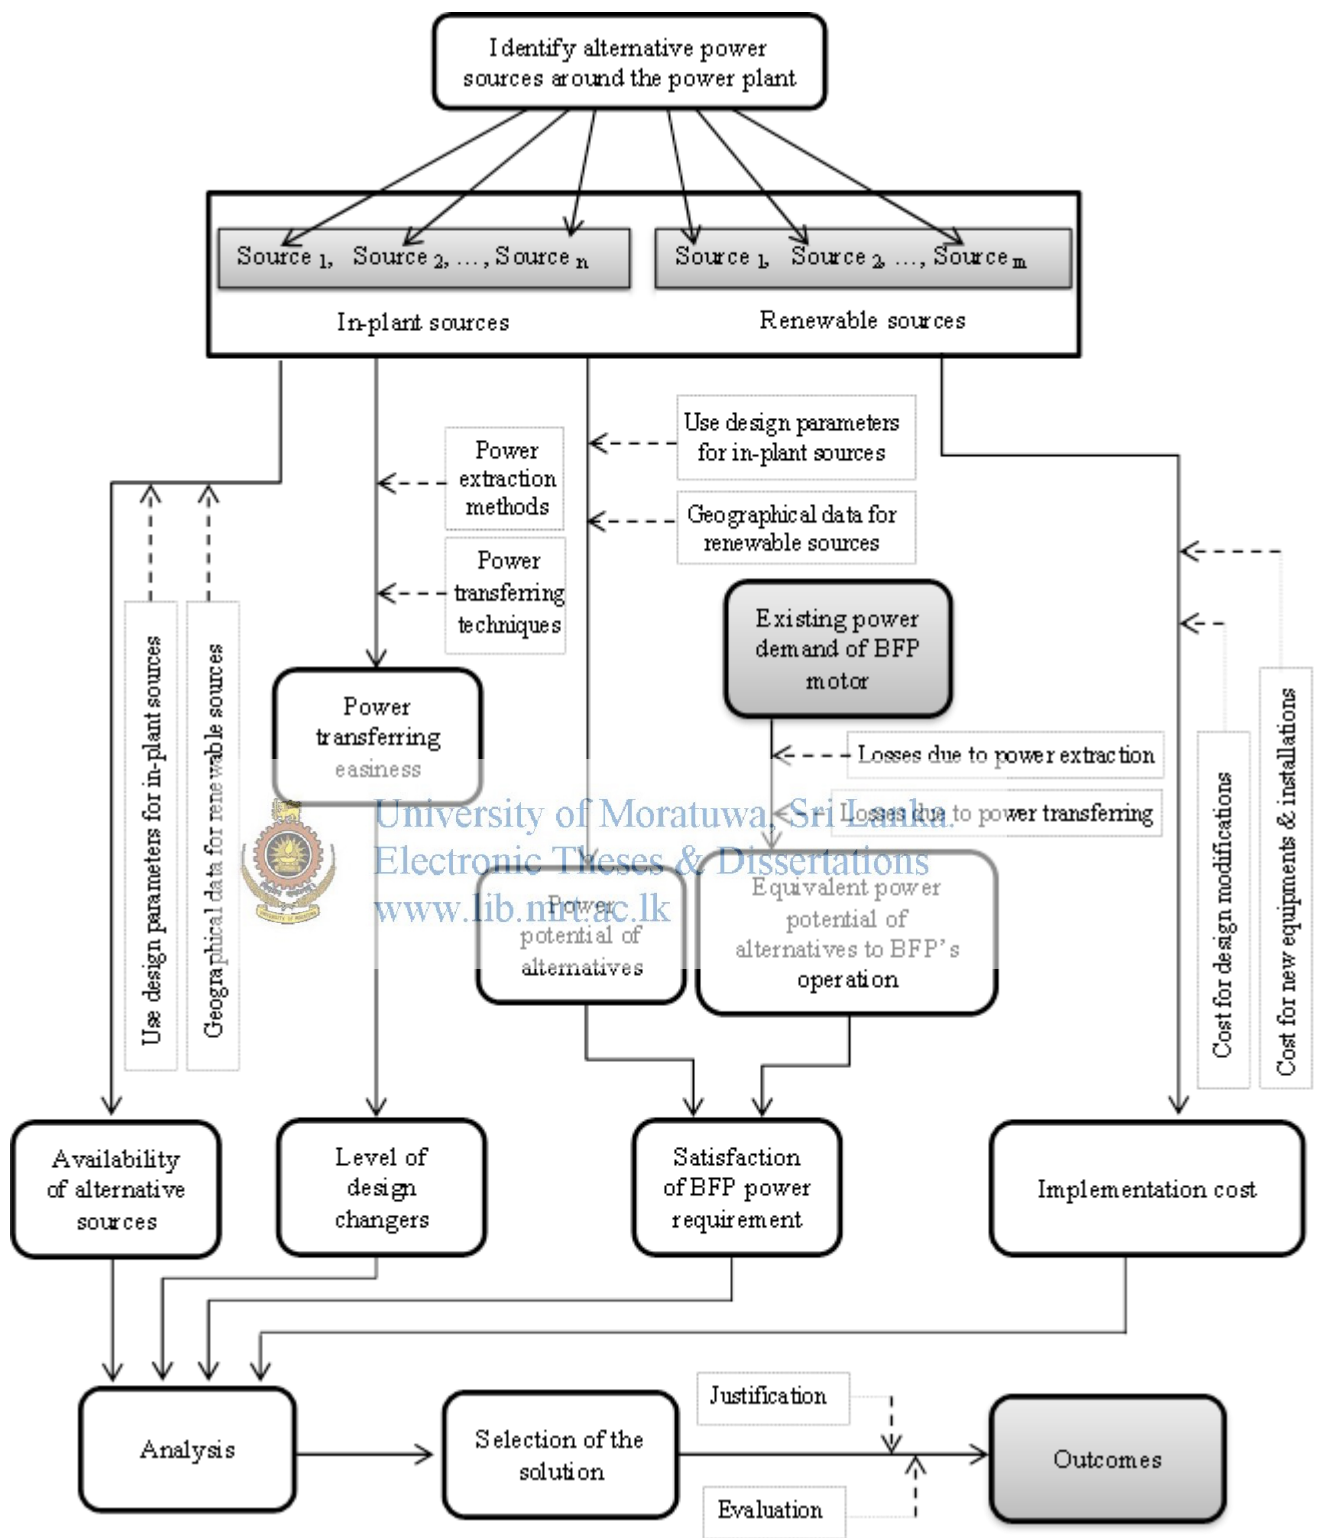

Figure 3.3.1 : Framework of the method

### **3.1 Identify the alternative power sources applicable to CPP**

Based on the results of the literature review, mechanical power, superheated steam, wind energy, sea wave energy, chemical energy and solar energy are the main power sources which can be seen in the operation of the coal power plants [75]. Furthermore these alternative sources are categorised as in-plant power sources and renewable power source [70]. In-plant power sources are decided by design parameters of the power plant and renewable power sources are decided by geographical and environmental factors of the area where the power plant is located.

### **3.2 Availability of the sources during the plant operation**

The availability of the power sources with reference to the power plant operation time is determined. Design parameters of the power plant are used for determining the availability of in-plant power sources. Geographical parameters, environmental factors and the dimensions of the site are used to determine the availability of the renewable energy sources.

#### **3.2.1 Determination the availability for mechanical sources**

As studied in literature review, mechanical torque power output of the main turbine shaft is only one power source which can be used practicably. The availability of the mechanical power is hundred percent during power plant operation time.

#### **3.2.2 Determination the availability for superheated steam**

As studied in the literature review, four steam sources which are extracted through the steam inlet of HP turbine, outlet of HP turbine, Inlet of IP turbine and outlet of IP turbine are dominant. In continuous operation of the power plant, these four extractions have been designed to extract from the main steam path of the steam cycle. Therefore the availability of the steam sources are hundred percent during the stable power plant operation time.

#### **3.2.3 Determination the availability for wind energy sources**

As pointed out in the literature review, the availability of wind energy sources is calculated by measuring geographical and environmental factors around the power

plant. If not, it is calculated using the previous annual data which have been recorded by a neighbouring institute.

### 3.2.4 Determination the availability for sea wave energy sources

As mentioned in the literature review, the availability of sea wave energy sources is calculated by measuring or reviewing geographical and environmental factors around the power plant. If not, it is calculated using previous annual data which have been recorded by a neighbouring institute.

### 3.2.5 Determination the availability for sea solar energy

As pointed out in the literature review, the availability of solar energy is calculated by measuring or reviewing geographical and environmental factors around the power plant. If not, it is calculated using previous annual data which have been recorded by a neighbouring institute.

### 3.2.6 Summarising the availability of alternative power sources

The availability of the sources is determined by using the most convenient data collection method related to the power plant. It is summarised as mentioned in Table 3.1.

University of Moratuwa, Sri Lanka  
Electronic Theses & Dissertations  
www.lib.mrt.ac.lk

Table 3.3.1 : Summarisation format of availability of alternatives

| Power source      | Availability (%) | Level                              |
|-------------------|------------------|------------------------------------|
| Mechanical power  | $X_1$            | (Excellent/Good/Average/Poor/Zero) |
| Superheated steam | $X_2$            | (Excellent/Good/Average/Poor/Zero) |
| Wind energy       | $X_3$            | (Excellent/Good/Average/Poor/Zero) |
| Sea wave energy   | $X_4$            | (Excellent/Good/Average/Poor/Zero) |
| Solar power       | $X_6$            | (Excellent/Good/Average/Poor/Zero) |

### **3.3 Power transferring easiness**

As mentioned in the literature review, easiness of power transferring to BFPs after the extraction of power is dependent on using power extraction method and power transferring technique. In addition, disturbances due to the existing structures and equipment of the power plant which are between power extracted point and BFPs are considered. Then power transferring easiness related to the main alternatives around a coal power plant is qualitatively evaluated.

#### **3.3.1 Easiness of mechanical power transferring**

As pointed out in the literature review, mechanical linkages are used for transmission of power, after extracting mechanical power by using all extraction methods. Power transferring with mechanical linkages in a coal power plant which is already constructed is extremely difficult.

#### **3.3.2 Easiness of power transferring related to steam sources**

Whatever methods are used to extract energy from steam, as mentioned in the literature review, it is transferred as a heat mass. Full steam piping, combination of steam and water piping or combination of steam and air ducting are used as power transferring techniques and their power transferring easiness is moderate.

#### **3.3.3 Easiness of wind power transferring**

As discussed in the literature review, using a wind turbine with mechanical linkages is very difficult to be introduced for constructed and currently operated power plant. Therefore the most suitable power transferring way is by using a generator coupled wind turbine and power conductors. In this case power is transmitted easily.

#### **3.3.4 Easiness of sea wave energy transferring**

As pointed out in the literature review, using of power conductors is a more easy transferring technique than the use of mechanical linkages. Therefore power transferring is easy after extracting energy through wave energy extractors.

### 3.3.5 Easiness of solar power transferring

As mentioned in the literature review, using of power conductors is only one power transferring technique for solar energy. Therefore power transferring related to the solar energy is easy.

### 3.3.6 Summarising the power transferring easiness of alternatives

Table 3.3.2 : Summary of the power transferring easiness

| Power source      | Extraction method       | Extraction technique | Easiness        |
|-------------------|-------------------------|----------------------|-----------------|
| Mechanical power  | (Direct couplings       | Mechanical linkage   | Ext. difficult. |
|                   | Gear mechanisms         |                      |                 |
|                   | Belt drives             |                      |                 |
|                   | Chain drives            |                      |                 |
| Superheated steam | Steam turbine           | Steam piping         | Moderate        |
|                   | Tube heat exchanger     | Steam/Water piping   |                 |
|                   | Metal heat exchanger    | Steam pipe/Air duct  |                 |
| Wind energy       | Wind turbine + Gen.     | Power conductors     | Easy            |
|                   | Wind turbine + RE       | Mechanical linkage   | Ext. difficult. |
| Sea wave energy   | Energy collector + Gen. | Power conductors     | Easy            |
|                   | Energy collector + RE   | Mechanical linkage   | Ext. difficult. |
| Solar power       | All solar collectors    | Power conductors     | Easy            |

### 3.4 Deciding the level of design changes

When implementing alternatives, the required level of design changes on the existing power plant is dependent on the transferring easiness of relevant transferring technique. According to the literature review, there are three main power transferring techniques are involved with the alternatives. The methodology which decides the level of the brequired design changes with reference to the alternatives and their power transferring easiness is summarised in Table 3.3.

Table 3.3.3 : Summary of required level of design changes

| Power source     | Power transferring technique | Level of required design changes |
|------------------|------------------------------|----------------------------------|
| Mechanical power | Mechanical linkages          | Total design change              |
| Steam sources    | Steam piping                 | Moderate changes                 |
| Wind energy      | Power conductors             | Minor change                     |
| Sea wave energy  | Power conductors             | Minor change                     |
| Solar energy     | Power conductors             | Minor change                     |

### 3.5 Power potential of alternatives

#### 3.5.1 Potential of mechanical torque power through main turbine shaft

As per the discussion which was done in the literature review, mechanical power potential is calculated by using the manual calculation based on theories or using a developed computer software like Engineering Equation Solver (EES).

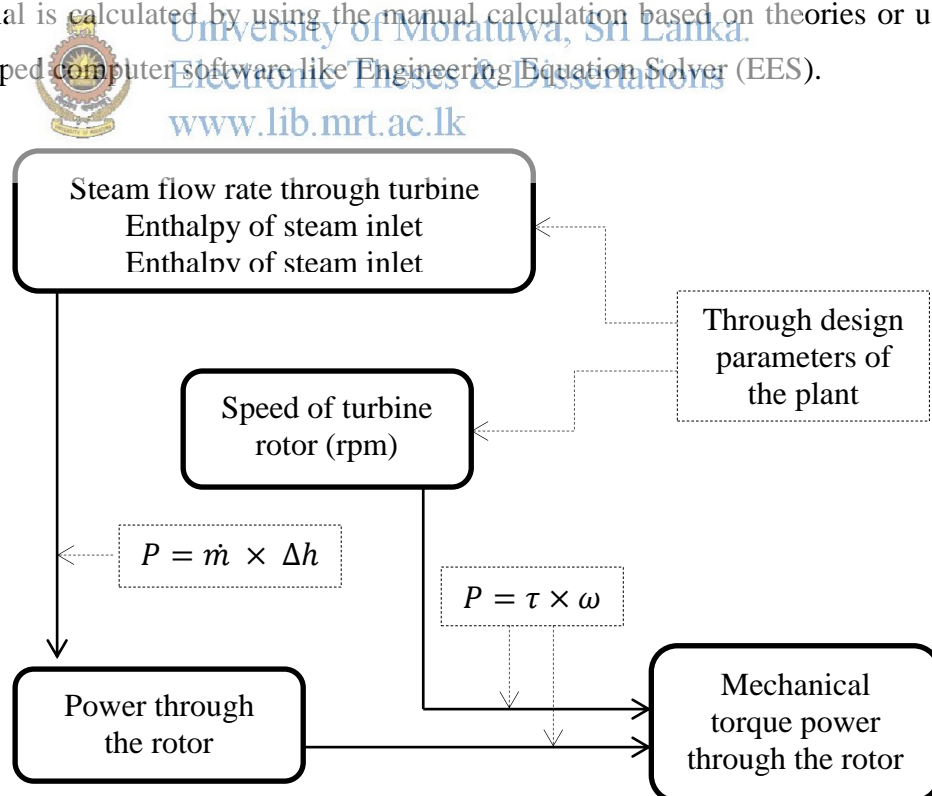

Figure 3.3.2 : Flow of calculations for mechanical source

The methodology applied for calculations and the flow of calculation shown in Figure 3.2 is used to calculate the mechanical power potential through a single turbine shaft. If the power plant has multiple turbine rotors, the total potential is calculated by adding power potential of each shaft after calculating for each shaft separately.

In addition to the calculation flow, three steps in two power conditions are involved to find the excessive torque power through the main turbine rotor.

**Step 01-** Calculation for total mechanical torque power of combined main turbine shaft at plant rated power condition (@  $P_{\text{rated}}$  MW condition).

- $P_{\text{rated}}$  MW is obtained by design parameters of the power plant

**Step 02-** Calculation for total mechanical torque power of combined main turbine shaft without taking power for BFPs from plant home load. (@  $P_x$  MW condition)

- $P_{\text{BFPs}}$  MW is component of home load which is consumed by BFPs at rated

conditions and  $P_x$  MW can be obtained as follows.

$$P_x \text{ MW} = P_{\text{rated}} \text{ MW} - P_{\text{BFPs}} \text{ MW}$$

**Step 03-** Calculation for excessive mechanical torque power and potential (Torque power potential difference between condition  $P_{\text{rated}}$  MW and  $P_x$  MW)

### 3.5.2 Potential of steam sources through four steam extractions

As mentioned in the literature review, four main steam extractions are available for process of feed water regeneration in a coal power plant. They are extracted before the main steam entering into HP turbine, cold reheated steam before entering the boiler, hot reheated steam before entering IP turbine and out stream of IP turbine. Excessive steam capacities are calculated as the difference of used steam at the above four locations with reference to the two power conditions which is explained in section 3.5.1. For the steam flow rates across each turbine rotor with reference to the two power conditions are calculated.

As per the discussion which was done in the literature review, these calculations are done manually based on theories or using developed computer software like Engineering Equation Solver (EES). The flow of calculation which is shown in Figure 3.3 is used to calculate the steam flow rate across a single turbine shaft.

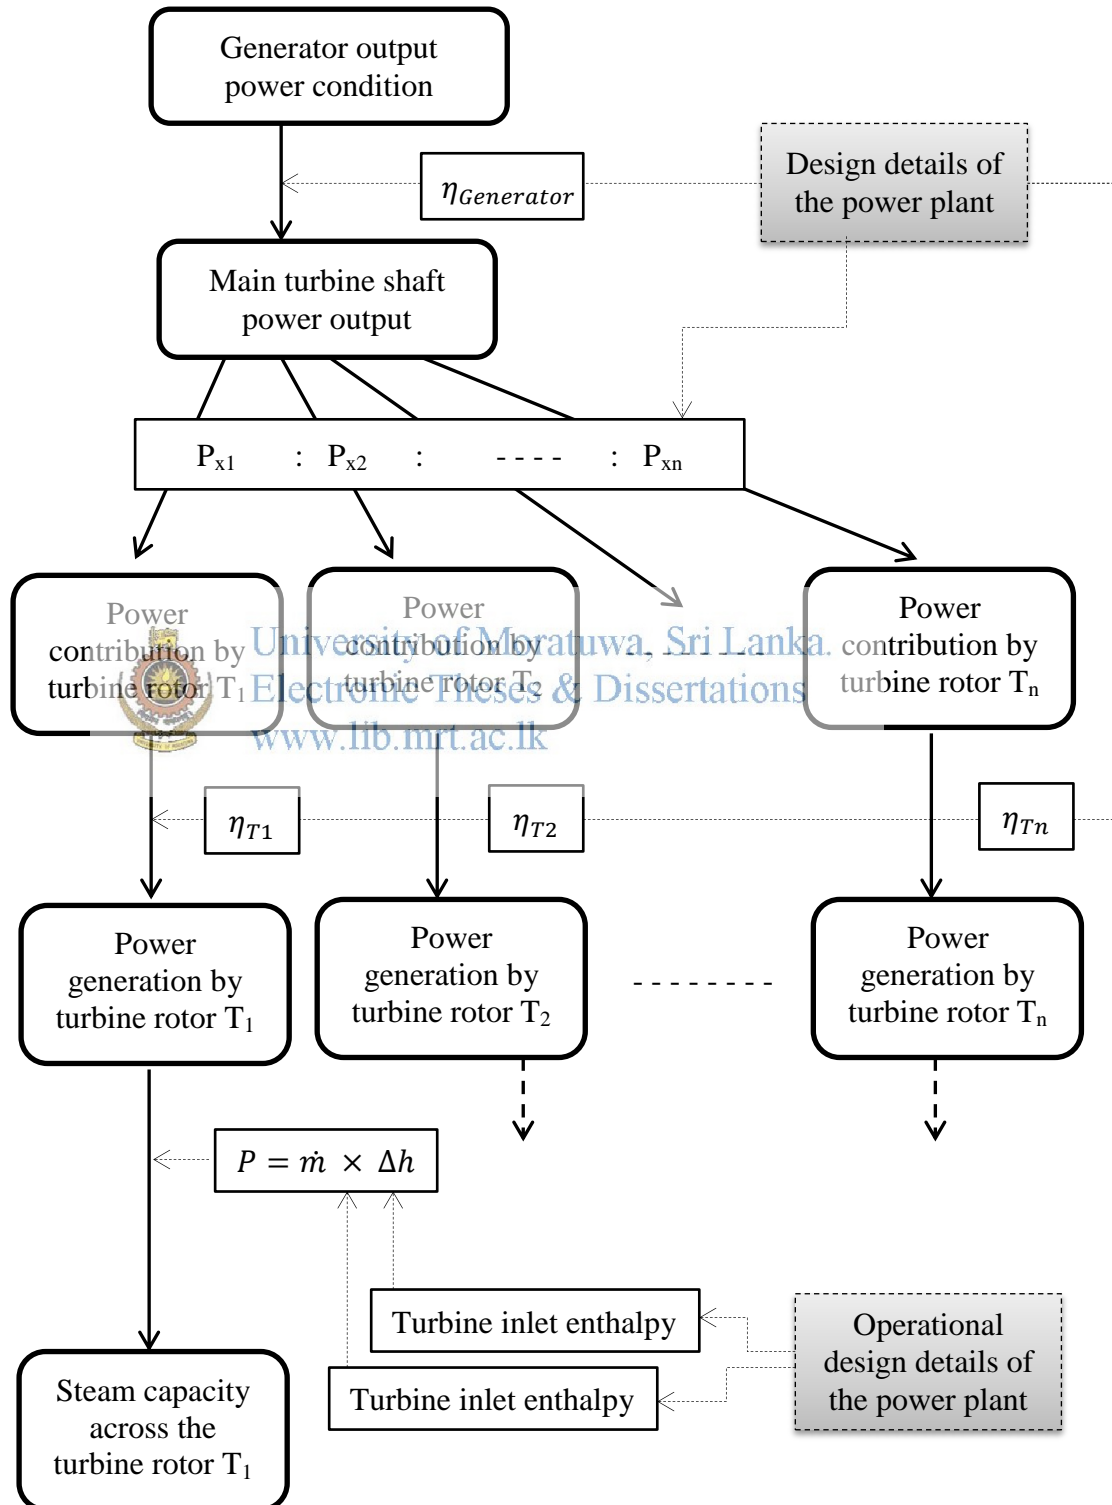

Figure 3.3.3 : Flow of calculation for steam sources

### 3.5.3 Wind power potential associated to the power plant

As discussed in the literature review, two strategies can be followed to estimate the wind power potential associated with the site of power plant. The first strategy is to do a study by adopting all the steps which are done in a feasibility study for new wind power farm. The second strategy is to check the ability and numbers of wind turbines according to the requirement of blade diameter. For this, the selected wind turbine type which has been practically installed and successfully operated in the neighbouring wind farm is used.

### 3.5.4 Sea wave energy potential associated to the power plant

According to the studies done in the literature review, potential of wave energy is dependent on the depth of the sea. (See Figure 4.7) By referring to the depth of the sea facing the site and length of the shore, sea wave energy potential is estimated.

### 3.5.5 Solar energy potential associated to the power plant

As per the literature review, solar energy density is extracted by solar density maps with reference to the considered area. Base on site construction details, area of bear land in power plant is calculated. Then solar energy potential of the site associated to the power plant is calculated.

### 3.5.6 Summary of power potential in the site of power plant

Table 3.3.4 : Summarisation format for the power potential of alternatives

| Alternative power source | Power potential in the site (MW) |
|--------------------------|----------------------------------|
| Mechanical power         | $P_{1@site}$                     |
| Steam sources            | $P_{2@site}$                     |
| Wind energy              | $P_{3@site}$                     |
| Sea wave energy          | $P_{4@site}$                     |
| Solar energy             | $P_{5@site}$                     |

### 3.6 Existing power demand of BFP motor

As discussed in the literature review, power demand of the existing motor of BFP is decided by BFP as well as its fluid coupler. There the required motor demand is calculated by using the calculation flow which is shown in Figure 3.4.

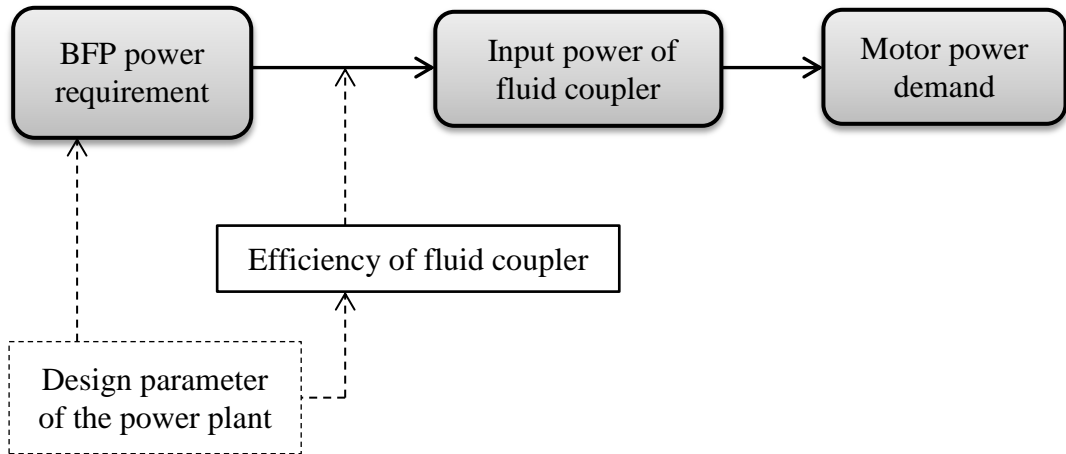

Figure 3.3.4 : Calculation flow for power demand of BFP motor

### 3.7 Equivalent power potential of alternatives to BFP's operation

Equivalent power potential which is demanded by motor of boiler feed pumps is calculated for each alternative power sources. This equivalent power is much higher than the demanded power by BFP motor, because of several losses are involved in power transferring mechanism between power extraction point and BFP motor. By considering design parameters of the power plant which were discussed in the literature review, equivalent power potential is calculated.

#### 3.7.1 Equivalent mechanical power potential

Equivalent power requirement is definitely higher than the power demand of BFP motor. Any mechanical power extraction method or transferring mechanism discussed in the literature review is used, considerable power losses occur. Therefore to calculate equivalent power potential, calculation flow shown in Figure 3.5 is applied.

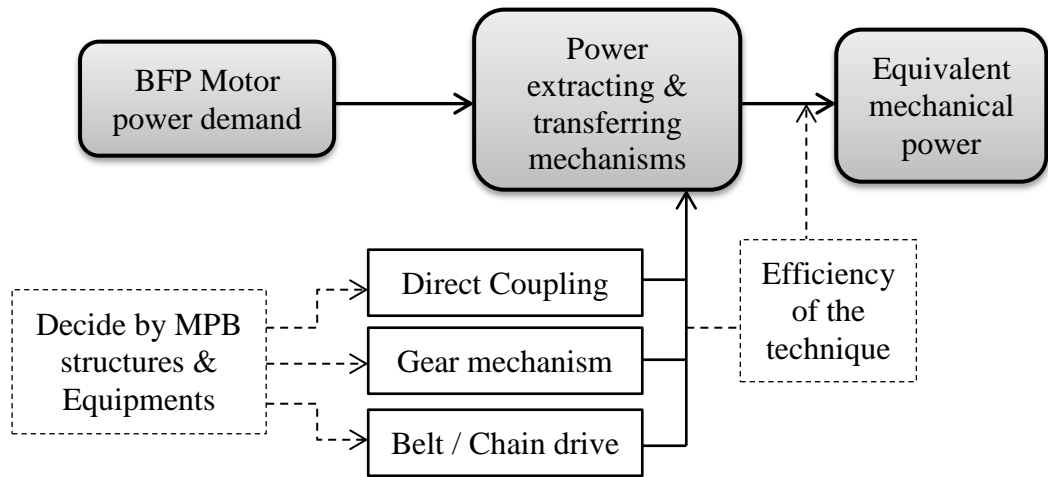

Figure 3.3.5 : Calculation flow of equivalent power for mechanical sources

### 3.7.2 Equivalent power potential for steam source

Any extraction method or transferring mechanism which was discussed in the literature review is used, considerable power losses occur. Therefore to calculate equivalent power potential calculation for steam sources, the flow shown in Figure 3.6 is applied.

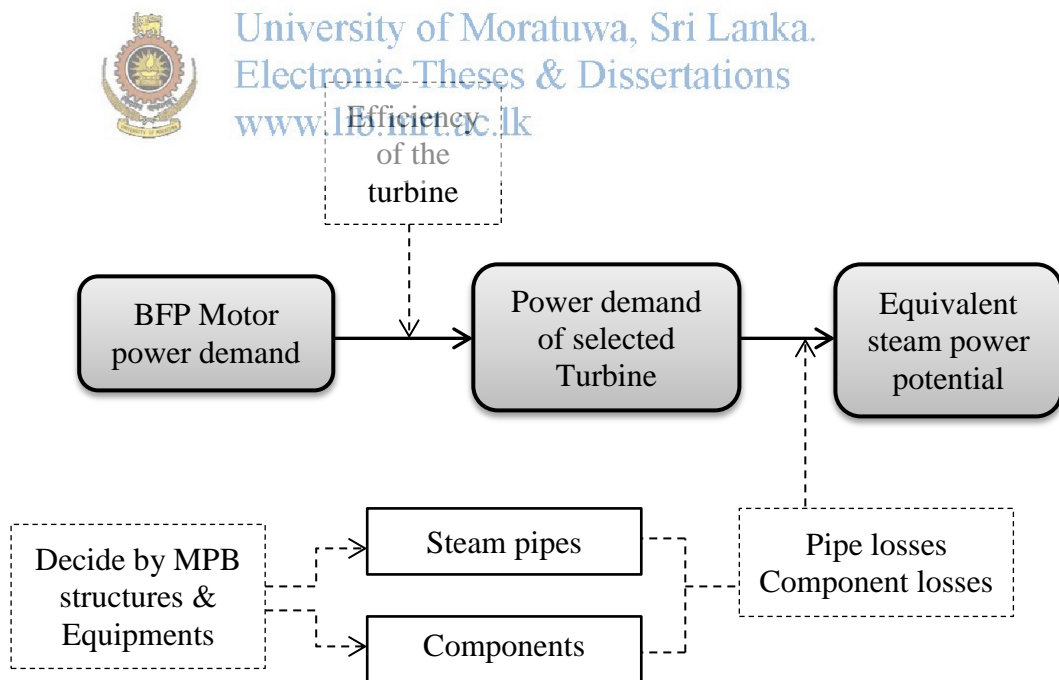

Figure 3.3.6 : Calculation flow of equivalent power for steam sources

### 3.7.3 Equivalent wind energy potential

To calculate equivalent power potential of wind energy, the calculation flow shown in Figure 3.7 is applied.

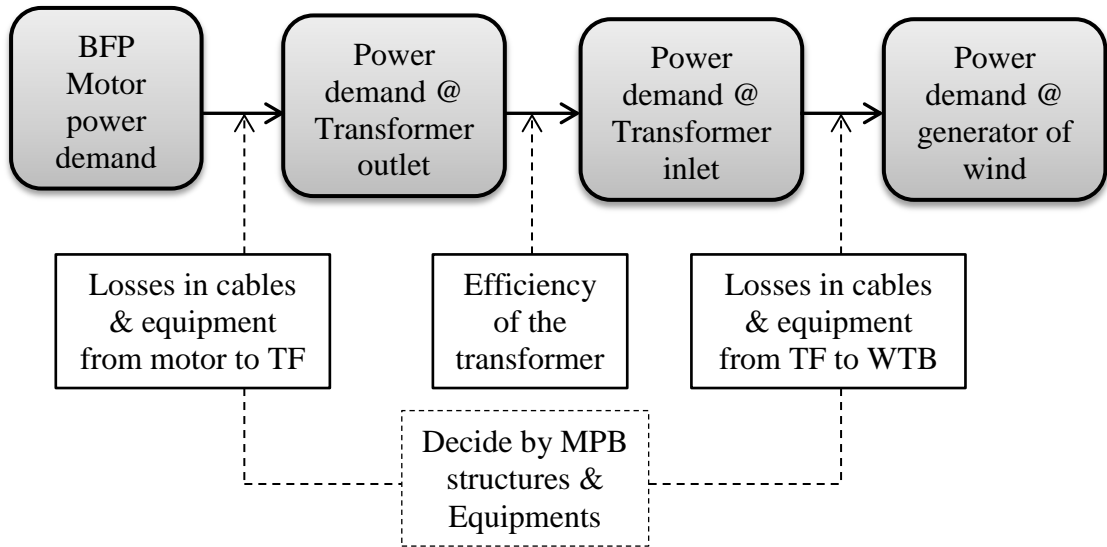

Figure 3.3.7 : Calculation flow of equivalent power for wind energy

### 3.7.4 Equivalent sea wave energy potential

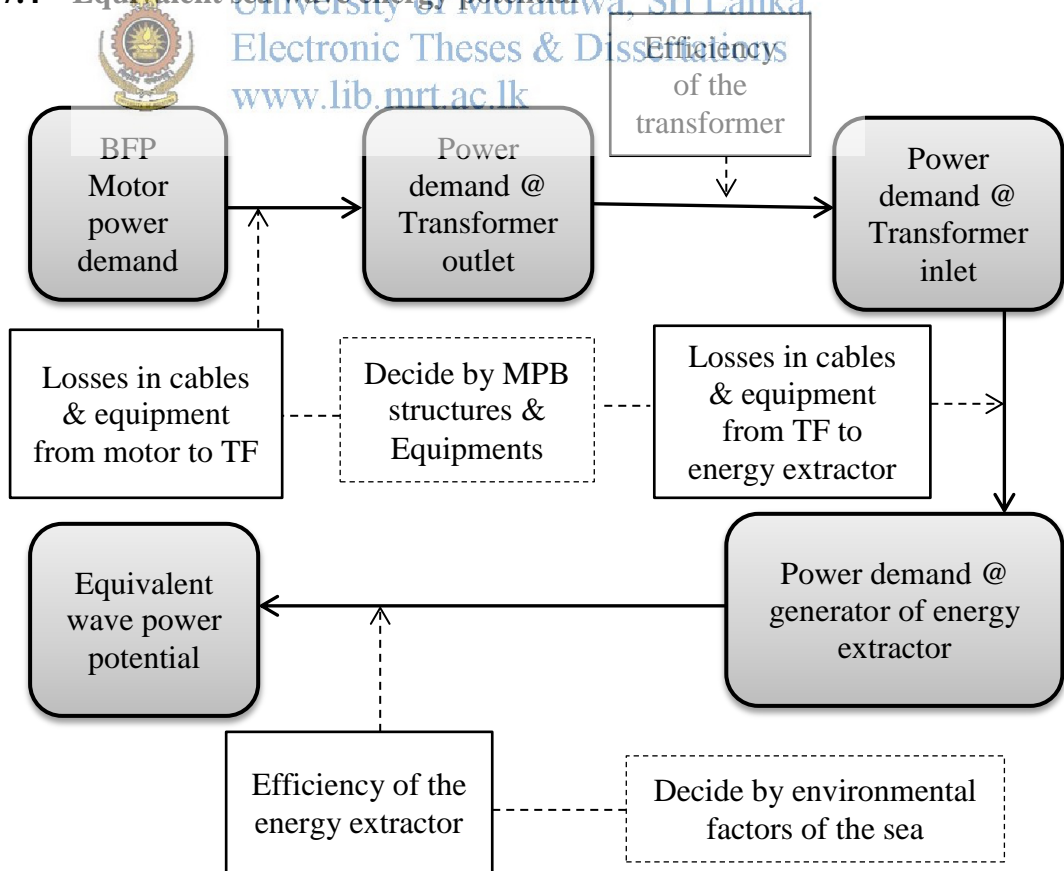

Figure 3.3.8 : Calculation flow of equivalent power for sea wave

To calculate equivalent power potential of sea wave energy, the calculation flow shown in Figure 3.8 is applied.

### 3.7.5 Equivalent solar power potential

To calculate equivalent power potential of sea wave energy, the calculation flow shown in Figure 3.9 is applied.

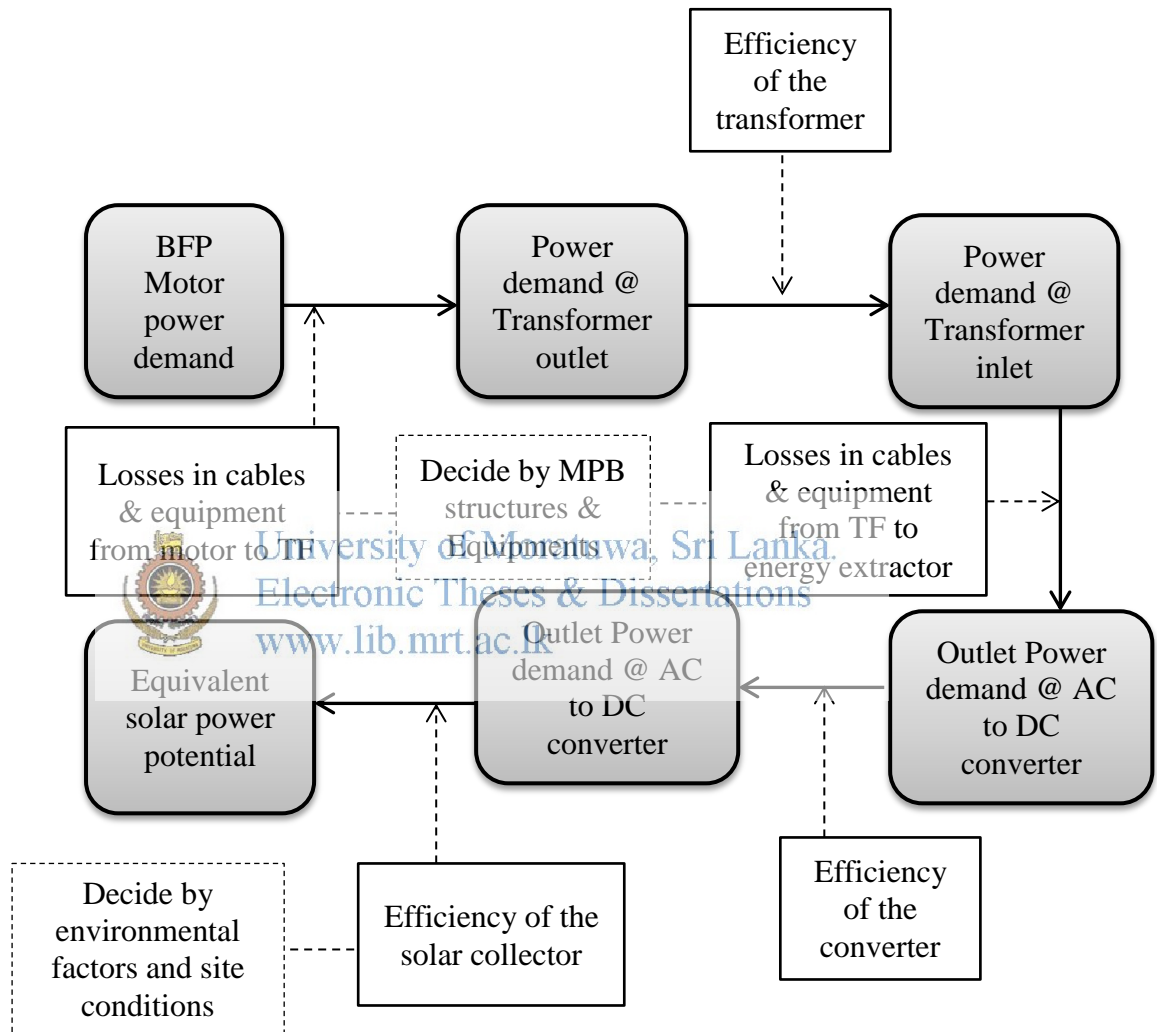

Figure 3.3.9 : Calculation flow of equivalent power for solar energy

### 3.7.6 Summary for equivalent power potential of alternatives

Table 3.3.5 : Summarisation format for equivalent potential of alternatives

| Alternative power source | Power potential in the site (MW) |
|--------------------------|----------------------------------|
| Mechanical power         | $P_{1\text{equivalent}}$         |
| Steam sources            | $P_{2\text{equivalent}}$         |
| Wind energy              | $P_{3\text{equivalent}}$         |
| Sea wave energy          | $P_{4\text{equivalent}}$         |
| Solar energy             | $P_{5\text{equivalent}}$         |

### 3.8 Satisfaction of BFP power requirement

Satisfaction of BFP power requirement for each source is checked by matching power potential of the source which was discussed in section 3.5 and equivalent power potential of the source which was discussed in section 3.7.

University of Moratuwa, Sri Lanka  
Electronic Theses & Dissertations  
www.lib.mrt.ac.lk

Table 3.3.6 : Summarisation format for BFP power satisfaction

| Alternative power source | Power potential in the site (MW) | Power potential in the site (MW) | Satisfactory level ( $P_{\text{@site}} - P_{\text{equivalent}}$ ) |
|--------------------------|----------------------------------|----------------------------------|---|
| Mechanical power         | $P_{1\text{@site}}$              | $P_{1\text{equivalent}}$         | Satisfy/Not satisfy   |
| Steam sources            | $P_{2\text{@site}}$              | $P_{2\text{equivalent}}$         | Satisfy/Not satisfy   |
| Wind energy              | $P_{3\text{@site}}$              | $P_{3\text{equivalent}}$         | Satisfy/Not satisfy   |
| Sea wave energy          | $P_{4\text{@site}}$              | $P_{4\text{equivalent}}$         | Satisfy/Not satisfy   |
| Solar energy             | $P_{5\text{@site}}$              | $P_{5\text{equivalent}}$         | Satisfy/Not satisfy   |

### **3.9 Implementation cost**

Based on the results of the literature review, implementation cost consists of two cost components. When estimating the implementation cost, both cost components are considered.

#### **3.9.1 Implementation cost for mechanical power sources**

When implementing mechanical power source for BFP system in an existing power plant, the cost for the new equipment and cost for design changes are considered as studied in the literature review. The cost for new equipment as well as design modification cost is dependent on site condition of the power plant.

#### **3.9.2 Implementation cost for steam sources**

As discussed in the literature review, the cost for relevant steam turbine, steam pipes and auxiliaries are required to be estimated under new equipment. The cost for new basement for steam turbine is estimated under modification cost. Installation cost is calculated separately.

#### **3.9.3 Implementation cost for sea wave energy**

The cost for modification, new equipment and their installation can be calculated as a new estimation by adopting all the steps which are done for a new sea wave power station. Otherwise, modification cost inside the power plant is calculated using the steps taken in section 3.9.3. The equipment and installation cost can be simply estimated by using cost estimation of similar previous power projects in the world.

#### **3.9.4 Implementation cost for solar energy**

All components related to the implementation cost can be calculated as a new estimation by adopting all the steps taken for a new solar power station. Else, equipment and installation cost can be simply estimated by using cost estimation of similar previous power projects in the world.

#### **3.9.5 Implementation cost for wind energy sources**

Modification cost inside the power plant is calculated separately. Because of this, modification is dependent on the existing design of the power plant. The cost for new

wind turbines and its installation can be estimated as a new estimation by adopting all the steps which are done for a new wind power farm. Otherwise it is calculated using installation cost data of wind turbines which have been practically installed and successfully operated in the neighbouring wind farm.

### 3.10 Analysis and selecting solutions

Key solutions are selected by analysing the availability of alternatives, required level of design changes, satisfaction of BFP requirement, by alternatives and implementation cost for alternatives. For this, details related to the above four factors are summarised. The summarised details which are in Table 3.7 are compared qualitatively and quantitatively.

Table 3.3.7 : Overall summarisation format for feasibility factors

| Factor       | Availability                                 | Requirement of design changes                             | Satisfaction of BFP's demand | Cost           |
|--------------|--|---|------------------------------|----------------|
| Power source |  |   |                              |                |
| Mechanical   | Excellent<br>Good<br>Average<br>Poor<br>Zero | Total design changes<br>Moderate changes<br>Minor changes | Satisfied<br>Not satisfied   | C <sub>1</sub> |
| Steam        | --do--                                       | --do--  | --do--                       | C <sub>2</sub> |
| Wind         | --do--                                       | --do--  | --do--                       | C <sub>3</sub> |
| Sea wave     | --do--                                       | --do--  | --do--                       | C <sub>4</sub> |
| Solar        | --do--                                       | --do--  | --do--                       | C <sub>5</sub> |

### **3.11 Evaluation and justification of the solutions**

The developed method is evaluated by applying to several coal power plants as case studies. If there are feasible solutions from these power plants according to the developed method, feasibility of solutions may be further justified by considering the following technical and economic factors.

- Grid supply power gain
- Annual power saving
- Annual financial saving
- Payback period
- Annual coal saving

### **3.12 Obtaining the outcomes**

The obtained positive responds of the factors which were discussed in section 3.11 are the outcomes of the developed method.

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
[www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

## CHAPTER 4 - CASE STUDY

### 4.1 Methodology for method evaluation

The developed method is evaluated by using a few cases. Some selected existing coal power plants which were constructed and are currently being operated with electric boiler feed pumps are used for that evaluation. In the scope of this study, Norochcholai coal power plant in Sri Lanka is used for the method evaluation. The required information and data are collected from the most popular alternative energy options using operational and design parameters of the Norochcholai coal power plant and supportive secondary data with relevant to the environment of Norochcholai area. To check some feasibility factors, calculations based on theories are done manually or by using computer software programs. After selecting the feasible solutions, results are justified by studying some technical and economic outcomes such as power gain, annual saving of energy, annual financial saving, payback period and annual coal saving for future.

### 4.2 Introduction of Norochcholai Coal Power Plant

The Norochcholai coal power plant is the largest and the first coal power plant in Sri Lanka. It is located in Norochcholai on the Kalpitiya Peninsula, approximately 12 km west of the city of Puttalam. Site coordinates - 8.0935613N 79.6392059E [49]. See Figure 4.2.

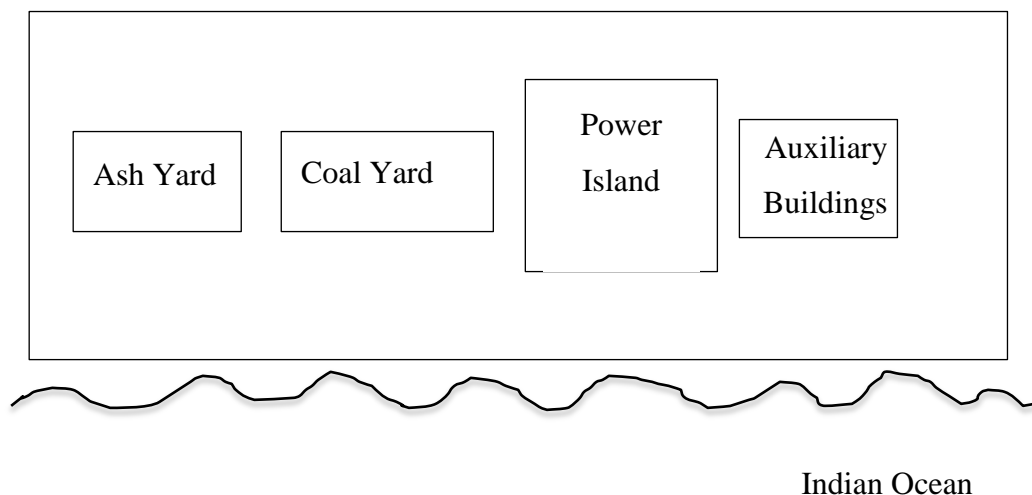

Figure 4.4.1 : Area utilisation of the site for buildings

Site dimensions - Norochcholai coal power plant is spread over large area with facing the Indian Ocean. See the attached drawing in appendix A for site layout of Norochcholai coal power plant. Rough area utilisation of the site is shown by Figure 4.1.

Figure 4.4.2 : Location of Norochcholai coal power plant

Source: <http://www.maplandia.com/sri-lanka>

### 4.3 Basic dimensions of the site

- Length of the whole site<sup>[51]</sup> = 2100 m
- Width of the whole site<sup>[51]</sup> = 420 m
- Area of the whole site (A) = 2100 m × 420 m  
= 882,000 m<sup>2</sup> = 0.882 km<sup>2</sup>
- Length of the ash yard<sup>[51]</sup> = 450 m
- Width of the ash yard<sup>[51]</sup> = 300 m
- Area of the ash yard (A<sub>1</sub>)<sup>[51]</sup> = 450 m × 300 m = 135,000 m<sup>2</sup>
- Length of the ash coal<sup>[51]</sup> = 600 m
- Width of the ash coal<sup>[51]</sup> = 300 m
- Area of the ash coal (A<sub>2</sub>)<sup>[51]</sup> = 600 m × 300 m = 180,000 m<sup>2</sup>
- Length of the power island<sup>[51]</sup> = 300 m
- Width of the power island<sup>[51]</sup> = 350 m
- Area of the power island (A<sub>3</sub>)<sup>[51]</sup> = 300 m × 350 m = 105,000 m<sup>2</sup>
- Area of the auxiliary buildings (A<sub>4</sub>)<sup>[51]</sup> = 300 m × 300 m = 90,000 m<sup>2</sup>
- Remaining available area in the site = 882,000 - (135,000 + 180,000 + 105,000 + 90,000)  
= 372,000 m<sup>2</sup> = 0.372 km<sup>2</sup>
- Length of the site facing to shore<sup>[51]</sup> = 2100 m

### 4.4 Case study based on Norochcholai coal power plant (NCPP)

All variable inputs, invariable inputs and four feasibility factors which are mentioned in method framework (See Figure 3.1) are studied applicable to the 300 MW Norochcholai coal power plant.

#### 4.4.1 Alternative power source related to the NCPP

##### ❖ In-plant alternative power sources

- Mechanical power through main turbine shaft
- Four steam extractions from steam cycle

❖ Renewable power sources

- Wind energy
- Sea wave energy
- Solar energy

#### 4.4.2 Determining the availability of alternatives in NCPP

Source availability with respected to the plant operation time is calculated

➤ Availability of mechanical power

Mechanical power through the turbine main shaft is almost fully available except unit start-up time [16]. Therefore the availability is assumed as 100%.

➤ Availability of steam sources

Superheated steam sources are almost fully available except unit start-up time [16]. Therefore the availability of steam sources are assumed as 100% during the unit stable operation time.

➤ Calculation for wind power availability around Norochcholai area

As studied in literature review, time-based availability is the most famous and commonly using method among the other three methods to calculate wind energy availability [51]. [www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

$$Availability = \frac{Wind\ turbine\ operation\ time}{Total\ time\ period}$$

There are few wind farms around the Norochcholai power plant. Therefore the annual wind turbine operation times which are listed in Table 4.1 are taken from these wind farms [52].

Table 4.4.1 : Annual operation hours of wind farms around Norochcholai

| Year | Operation time of wind turbines (hrs) |             |          |
|------|---------------------------------------|-------------|----------|
|      | Daily Life Energy                     | Nirmalapura | PowerGen |
| 2012 | 7508                                  | --          | --       |
| 2013 | 7876                                  | 7240        | 7323     |
| 2014 | 7032                                  | 7129        | 7080     |

$$\text{Annual wind availability} = \frac{\text{Total operation hours of wind turbines}}{365 \times 24 \text{ h}} \times 100$$

Table 4.4.2 : Annual wind availability of wind farms around Norochcholai

| Year        | Daily Life Energy | Nirmalapura | PowereGen |
|-------------|-------------------|-------------|-----------|
| 2012        | 85.71%            | --          | --        |
| 2013        | 89.90%            | 82.65%      | 83.60%    |
| 2014        | 80.27%            | 81.38%      | 80.82%    |
| <b>Avg.</b> | 85.29%            | 82.02%      | 82.21%    |

$$\therefore \text{Average wind availability around Norochcholai} = \frac{85.29\% + 82.02\% + 82.21\%}{3}$$

Average wind availability around Norochcholai = 83.17%

➤ Calculation for availability of wave energy around Norochcholai

As mentioned in literature review, capacity of energy which is extracted through sea wave is decided by height of the waves [47]. The height is depended on the seasonal wind patterns [53]. Therefore monsoon patterns, seasonal wind patterns and sea wave height in the sea near Norochcholai area are considered to calculate the availability of wave energy.

- Monsoon period for Norochcholai area is from May to October [54].
- According to the report of Wave run-up estimates at gentle beaches in the northern Indian Ocean, seasonal variation of wind speed and sea wave height are shown in the Figure 4.3.

- According to Figure 4.3, five months in a year around Norochcholai sea area is caught by southwest monsoon season and during the off-season average sea wave height is less than 1m.
- For the practicable wave energy extraction, it is required more than 1m average height of sea waves [47].

$$\therefore \text{Annual availability of sea wave energy in Norochcholai} = \frac{5 \text{ Months}}{12 \text{ Months}} \times 100\%$$

Figure 4.4.3 : Seasonal variation of wind speed and wave height in NIO

Source: <http://www.oceandocs.org/bitstream/1834/4557/1/Wave%20runup.pdf>

$$\text{Annual availability of sea wave energy in Norochcholai} = 41.67\%$$

➤ Calculation for availability of solar power around Norochcholai

As mentioned in literature review, annual availability of the solar power source is depended on numbers of the days with clear sky or numbers of sunny days in a year [48]. Puttalam is the most near weather station for Norochcholai area. Therefore collected weather data from Puttalam station are almost equal to Norochcholai area. Past records for numbers of sunny days for Puttalam area shown in the Table 4.3 [55].

Table 4.4.3 : Numbers of sunny days in a year in Puttalam city

| Year | Numbers of sunny days |     |     |     |     |     |     |     |     |     |     |     |       |
|------|-----------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-------|
|      | Jan                   | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec | Total |
| 2014 | 26                    | 26  | 28  | 29  | 30  | 30  | 29  | 28  | 18  | 12  | 15  | 22  | 293   |
| 2013 | 28                    | 27  | 29  | 29  | 31  | 30  | 28  | 26  | 21  | 16  | 19  | 24  | 308   |

$$\therefore \text{Day time solar power availability} = \frac{\text{Sunny days in a year}}{365} \times 100\%$$

$$\text{Day time solar power availability in 2014} = \frac{293}{365} \times 100\% = 80.27$$

$$\text{Day time solar power availability in 2013} = \frac{308}{365} \times 100\% = 84.38$$

 University of Moratuwa, Sri Lanka.  
 Electronic Theses & Dissertations  
 www.lib.mru.ac.lk

When consider the real availability with reference to the power plant operation time, these percentages are half. Because of the power plant is operated continuously in day time as well as in night time.

$$\text{Real time solar power availability} = \frac{\text{Availability in Day time}}{2}$$

$$\therefore \text{Real time solar power availability in 2014} = \frac{80.27\%}{2} = 40.14\%$$

$$\therefore \text{Real time solar power availability in 2013} = \frac{84.38\%}{2} = 42.19\%$$

$$\text{Average solar power availability} = \frac{40.14\% + 42.19\%}{2} = 41.17\%$$

Table 4.4.4 : Availability of power sources in NCPP

| Power source      | Availability (%) | Level     |
|-------------------|------------------|-----------|
| Mechanical power  | 100              | Excellent |
| Superheated steam | 100              | Excellent |
| Wind energy       | 83.17            | Good      |
| Sea wave energy   | 41.67            | Average   |
| Solar power       | 41.17            | Average   |

#### 4.4.3 Power transferring easiness in NCPP

##### ❖ Transferring easiness of mechanical power

According to the equipment layout drawing of the main power block (MPB), the main turbine is located at 12.6m level. BFPs are located at 0m level. Many disturbances due to building structures and equipment can be seen between 12.6m level and 0m level [50] (See appendix B). As per the studies which were done in the literature review, mechanical linkages are used to transmit power between the turbine shaft and BFP. Therefore power transferring easiness is extremely difficult when using mechanical linkages with that kind of disturbance.

##### ❖ Transferring easiness for steam sources

As discussed in the literature review, using a steam turbine with steam piping is the most efficient and common way to extract and transfer energy from a steam source. As per the factors which are shown on the general arrangement drawing, power can be transferred with newly designed steam pipe system although structural and equipment disturbances are there. Therefore extracted power through steam sources can be transferred with moderate easiness in the Norochcholai power plant.

- ❖ Power transferring easiness from wind sources  
According to the site layout drawing which is attached to appendix A, considerable free area can be identified in the site of Norochcholai power plant. When considering the power transferring easiness based on the literature review, the most suitable way is to use an electric generator coupled with wind turbine and power conductors. Therefore the power transferring of wind energy is easy in relation to Norochcholai power plant.
- ❖ Power transferring easiness from sea wave energy  
According to the site layout drawing which is attached to appendix A, western border with 2100 m length of the site of Norochcholai power plant faces to the Indian ocean. When considering the power transferring easiness based on the literature review, the most suitable way is to use an electric generator and wave energy extractor with power conductors. Therefore transferring after power extracting from sea wave energy is easy in relation to the Norochcholai power plant.
- ❖ Power transferring easiness from solar energy  
As discussed in the literature review, flat-plate collector method for solar energy extraction is more convenient and suitable for a partially occupied site like of Norochcholai power plant. Power transferring easiness for solar energy is easy due to the use of power conductors.

Table 4.4.5 : Level of power transferring easiness for alternatives in NCPP

| Power source     | Power transferring technique | Level of easiness   |
|------------------|------------------------------|---------------------|
| Mechanical power | Mechanical linkages          | Extremely difficult |
| Steam sources    | Steam piping                 | Moderate            |
| Wind energy      | Power conductors             | Easy                |
| Sea wave energy  | Power conductors             | Easy                |
| Solar energy     | Power conductors             | Easy                |

#### 4.4.4 Level of required design change in NCPP

- ❖ Level of required design change when using mechanical linkages

According to the general arrangement drawing of MPB in NCPP (See appendix B), many structures and equipment are affected when power transferring by using mechanical linkages. Therefore it needs a total design change on existing MPB.

- ❖ Level of required design change when using steam piping

Although new steam piping system is required to newly design, extracted power through steam sources can be transferred with some considerable changes in existing design. No need to change entire design of MPB.

- ❖ Level of required design change when using power conductors

As discussed in literature review, cable trenches or cable trays are used to lay power conductors. According to the equipment arrangement drawing of MPB in NCPP (See appendix C), there are enough spaces to lay cables with minor modifications

Table 4.4.6: Required level of changes on MPB in NCPP

| Power source     | Power transferring technique | Level of design change in MPB |
|------------------|------------------------------|-------------------------------|
| Mechanical power | Mechanical linkages          | Total design change           |
| Steam sources    | Steam piping                 | Moderate changes              |
| Wind energy      | Power conductors             | Minor change                  |
| Sea wave energy  | Power conductors             | Minor change                  |
| Solar energy     | Power conductors             | Minor change                  |

#### 4.4.5 Power potential of alternatives in site of NCPP

➤ Potential of mechanical torque power through main turbine shaft

The existing BFPs in NCPP are energised by a fraction of the main generator output power. During the generation of 300 MW, which is in power plant rated capacity, 10.78 MW power out of 300 MW is consumed by BFPs [13]. Therefore it needs to calculate the turbine shaft torque at 300 MW as well as at 289.22 MW. Assume that the required 10.78 MW power for BFP energising is not taken through the main generator power output.

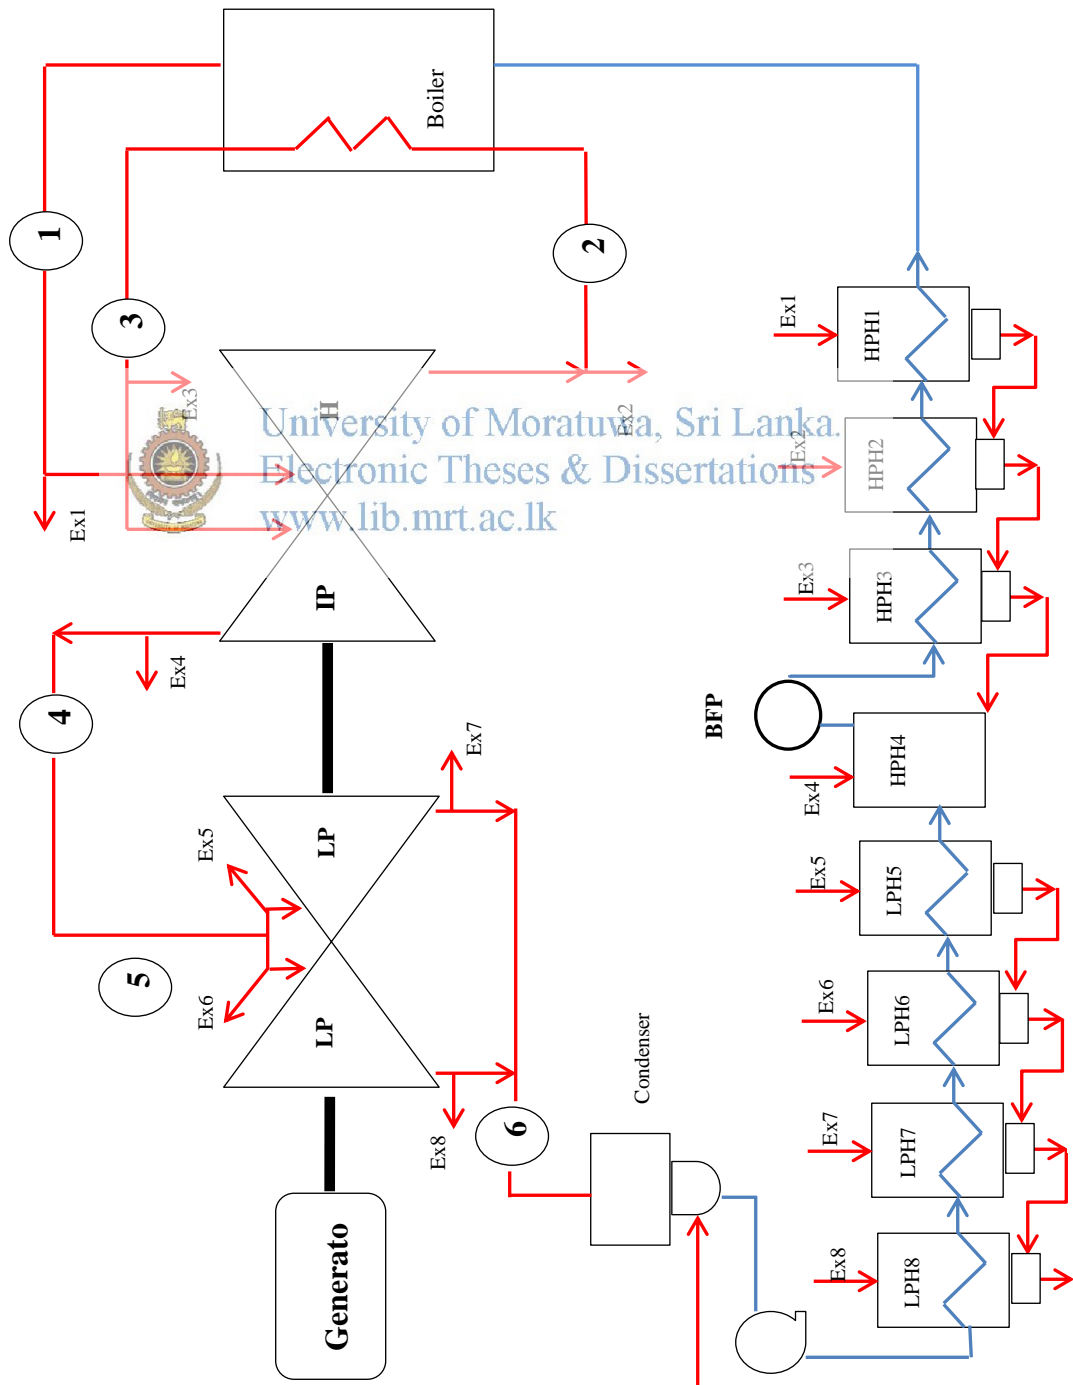

Figure 4.4.4 : Thermal cycle in Norochcholai coal power plant

❖ Operation parameters in Norochcholai power plant at its rated power capacity

- Boiler operation conditions @ 300 MW capacity

$$\text{Boiler main steam pressure} = 16.7 \text{ MPa}$$

$$\text{Boiler main steam temperature} = 538 \text{ }^\circ\text{C}$$

- Operational parameters @ 300 MW (plant rated power) related to the point #1 of Figure 4.4 [16].

$$\text{Steam flow rate from boiler} = \dot{m}_{1@300MW} = 964 \text{ T/h}$$

$$\text{Enthalpy} = h_{1@300MW} = 3396.9 \text{ kJ/kg}$$

$$\text{Steam flow rate through Extraction \#1} = \dot{m}_{Ex1} = 71.04 \text{ T/h}$$

- Operational parameters @ 300 MW (plant rated power) related to the point #2 of Figure 4.4 [16].

$$\text{Cold Re – heater steam flow rate to boiler} = \dot{m}_{1@300MW} = 803.75 \text{ T/h}$$

$$\text{Enthalpy} = h_{2@300MW} = 3048.9 \text{ kJ/kg}$$

$$\text{Steam flow rate through Extraction \#2} = \dot{m}_{Ex2} = 76.23 \text{ T/h}$$

- Operational parameters @ 300 MW (plant rated power) related to the point #3 of Figure 4.4[16].

$$\text{Hot Re – heater steam flow rate from boiler} = \dot{m}_{3@300MW} = 803.75 \text{ T/h}$$

$$\text{Enthalpy} = h_{3@300MW} = 3535.9 \text{ kJ/kg}$$

$$\text{Steam flow rate through Extraction \#3} = \dot{m}_{Ex3} = 31.01 \text{ T/h}$$

- Operational parameters @ 300 MW (plant rated power) related to the point #4 of Figure 4.4 [16].

$$\text{Steam flow rate of IP outlet} = \dot{m}_{4@300MW} = 733.67 \text{ T/h}$$

$$\text{Enthalpy} = h_{4@300MW} = 3168.7 \text{ kJ/kg}$$

$$\text{Steam flow rate through Extraction \#4} = \dot{m}_{Ex4} = 41.12 \text{ T/h}$$

- Operational parameters @ 300 MW (plant rated power) related to the point #5 of Figure 4.4 [16].

$$\text{Steam flow rate into LP turbine} = \dot{m}_{5@300MW} = 733.67 \text{ T/h}$$

$$\text{Enthalpy} = h_{5@300MW} = 3168.7 \text{ kJ/kg}$$

$$\text{Steam flow rate through Extraction \#5} = \dot{m}_{Ex5} = 41.27 \text{ T/h}$$

$$\text{Steam flow rate through Extraction \#6} = \dot{m}_{Ex6} = 25.43 \text{ T/h}$$

- Operational parameters @ 300 MW (plant rated power) related to the point #6 of Figure 4.4 [16].

$$\text{Steam flow rate into condenser} = \dot{m}_{6@300MW} = 613.25 \text{ T/h}$$

$$\text{Enthalpy} = h_{6@300MW} = 2368.6 \text{ kJ/kg}$$

$$\text{Steam flow rate through Extraction \#7} = \dot{m}_{Ex7} = 28.66 \text{ T/h}$$

$$\text{Steam flow rate through Extraction \#8} = \dot{m}_{Ex8} = 25.44 \text{ T/h}$$

University of Moratuwa, Sri Lanka  
Electronic Theses & Dissertations

**Step: 01**-Calculation for Mechanical torque of main turbine shaft @ 300 MW  
(Plant's rated power)

- ✓ Torque through HP rotor

$$P = \dot{m} \times \Delta h \quad ; \text{Where } P \text{ – power in kW}$$

$$\dot{m} \text{ – steam flow rate in kg/s}$$

$$\Delta h \text{ – enthalpy difference in kJ/kg}$$

$$P_{HP@300MW} = (\dot{m}_{1@300MW} - \dot{m}_{Ex1}) \times (h_{1@300MW} - h_{2@300MW})$$

$$P_{HP@300MW} = (964 - 71.04) \times \frac{10^3}{60 \times 60} \text{ kg/s} \times (3396.9 - 3048.9) \text{ kJ/kg}$$

$$P_{HP@300MW} = 86,245.05 \text{ kW} = 86.25 \text{ MW}$$

$$P_{HP@300MW} = \tau_{HP@300MW} \times \omega_{@3000rpm}$$

$$86,245.05 = \tau_{HP@300MW} \times 3000 \times \frac{2\pi}{60}$$

$$\tau_{HP@300MW} = 274.57 \text{ kNm}$$

✓ Torque through IP rotor

$$P_{IP@300MW} = (\dot{m}_{3@300MW} - \dot{m}_{Ex3}) \times (h_{3@300MW} - h_{4@300MW})$$

$$P_{IP@300MW} = (803.75 - 31.0) \times \frac{10^3}{60 \times 60} \text{ kg/s} \times (3535.9 - 3168.7) \text{ kJ/kg}$$

$$P_{IP@300MW} = 78,820.5 \text{ kW} = 78.82 \text{ MW}$$

$$P_{IP@300MW} = \tau_{IP@300MW} \times \omega_{@3000rpm}$$

$$78,820.5 = \tau_{IP@300MW} \times 3000 \times \frac{2\pi}{60}$$

$$\tau_{IP@300MW} = 250.9 \text{ kNm}$$

✓ Torque through LP rotors

$$P_{LP@300MW} = (\dot{m}_{4@300MW} - \dot{m}_{Ex5} - \dot{m}_{Ex6}) \times (h_{4@300MW} - h_{6@300MW})$$

$$P_{LP@300MW} = (733.67 - 41.27 - 25.43) \times \frac{10^3}{60 \times 60} \text{ kg/s} \times (3168.7 - 2368.6) \text{ kJ/kg}$$

$$P_{LP@300MW} = 148,197.03 \text{ kW} = 148.2 \text{ MW}$$

$$P_{LP@300MW} = \tau_{LP@300MW} \times \omega_{@3000rpm}$$

$$148,197.03 = \tau_{LP@300MW} \times 3000 \times \frac{2\pi}{60}$$

$$\tau_{LP@300MW} = 471.73 \text{ kNm}$$

✓ Total torque output through turbine main shaft @ 300 MW

$$\tau_{turbine@300MW} = \tau_{HP@300MW} + \tau_{IP@300MW} + \tau_{LP@300MW}$$

$$\tau_{turbine@300MW} = 274.57 \text{ kNm} + 250.9 \text{ kNm} + 471.73 \text{ kNm}$$

$$\tau_{turbine@300MW} = 997.2 \text{ kNm}$$

❖ Operation parameters in Norochcholai power plant at 289.22 MW power capacity

- Boiler operation conditions @ 289.22 MW capacity

$$\text{Boiler main steam pressure} = 16.7 \text{ MPa}$$

$$\text{Boiler main steam temperature} = 538 \text{ }^\circ\text{C}$$

- Operational parameters @ 289.22 MW related to the point #1 of Figure 4.4 [16].

$$\text{Steam flow rate from boiler} = \dot{m}_{1@289.22\text{MW}} = 932.45 \text{ T/h}$$

$$\text{Enthalpy} = h_{1@289.22\text{MW}} = 3396.9 \text{ kJ/kg}$$

$$\text{Steam flow rate through Extraction \#1} = \dot{m}_{Ex1} = 71.04 \text{ T/h}$$

- Operational parameters @ 289.22 MW related to the point #2 of Figure 4.4 [16].

$$\text{Cold Re – heater steam flow rate to boiler} = \dot{m}_{2@289.22\text{MW}} = 785.18 \text{ T/h}$$

$$\text{Enthalpy} = h_{2@289.22\text{MW}} = 3048.9 \text{ kJ/kg}$$

$$\text{Steam flow rate through Extraction \#2} = \dot{m}_{Ex2} = 76.23 \text{ T/h}$$

University of Moratuwa, Sri Lanka

$$\text{Steam flow rate through Extraction \#5} = \dot{m}_{Ex5} = 41.27 \text{ T/h}$$

$$\text{Steam flow rate through Extraction \#6} = \dot{m}_{Ex6} = 25.43 \text{ T/h}$$

- Operational parameters @ 289.22 MW related to the point #6 of Figure 4.4 [16].

$$\text{Steam flow rate into condenser} = \dot{m}_{6@289.22MW} = 590.94 \text{ T/h}$$

$$\text{Enthalpy} = h_{6@289.22MW} = 2368.6 \text{ kJ/kg}$$

$$\text{Steam flow rate through Extraction \#7} = \dot{m}_{Ex7} = 28.66 \text{ T/h}$$

$$\text{Steam flow rate through Extraction \#8} = \dot{m}_{Ex8} = 25.44 \text{ T/h}$$

**Step 02:-** Calculation for Mechanical torque of main turbine shaft @ 289.22 MW

- ✓ Torque through HP rotor

$$P_{HP@289.22MW} = (\dot{m}_{1@289.22MW} - \dot{m}_{Ex1}) \times (h_{1@289.22MW} - h_{2@289.22MW})$$

$$P_{HP@289.22MW} = (932.45 - 71.04) \times \frac{10^3}{60 \times 60} \text{ kg/s} \times (3396.9 - 3048.9) \text{ kJ/kg}$$

$$P_{HP@289.22MW} = 83,269.63 \text{ kW} = 83.27 \text{ MW}$$

$$P_{HP@289.22MW} = \tau_{HP@289.22MW} \times \omega_{@3000rpm}$$

$$83,269.63 = \tau_{HP@289.22MW} \times 3000 \times \frac{2\pi}{60}$$

$$\tau_{HP@289.22MW} = 265.05 \text{ kNm}$$

- ✓ Torque through IP rotor

$$P_{IP@289.22MW} = (\dot{m}_{3@289.22MW} - \dot{m}_{Ex3}) \times (h_{3@289.22MW} - h_{4@289.22MW})$$

$$P_{IP@289.22MW} = (778.11 - 31.0) \times \frac{10^3}{60 \times 60} \text{ kg/s} \times (3535.9 - 3168.7) \text{ kJ/kg}$$

$$P_{IP@289.22MW} = 76,205.22 \text{ kW} = 76.20 \text{ MW}$$

$$P_{IP@289.22MW} = \tau_{IP@289.22MW} \times \omega_{@3000rpm}$$

$$76,205.22 = \tau_{IP@289.22MW} \times 3000 \times \frac{2\pi}{60}$$

$$\tau_{IP@289.22MW} = 242.5 \text{ kNm}$$

✓ Torque through LP rotors

$$P_{LP@289.22MW} = (\dot{m}_{4@289.22MW} - \dot{m}_{Ex5} - \dot{m}_{Ex6}) \times (h_{4@289.22MW} - h_{6@289.22MW})$$

$$P_{LP@289.22MW} = (705.98 - 41.27 - 25.43) \times \frac{10^3}{60 \times 60} \times (3168.7 - 2368.6) \text{ kJ/s}$$

$$P_{LP@289.22MW} = 142,079.98 \text{ kW} = 142.08 \text{ MW}$$

$$P_{LP@289.22MW} = \tau_{LP@289.22MW} \times \omega_{@3000rpm}$$

$$142,079.98 = \tau_{LP@289.22MW} \times 3000 \times \frac{2\pi}{60}$$

$$\tau_{LP@289.22MW} = 452.25 \text{ kNm}$$

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
www.lib.mrt.ac.lk

✓ Total torque output through turbine main shaft

$$\tau_{turbine@289.22MW} = \tau_{HP@289.22MW} + \tau_{IP@289.22MW} + \tau_{LP@289.22MW}$$

$$\tau_{turbine@289.22MW} = 265.05 \text{ kNm} + 242.5 \text{ kNm} + 452.25 \text{ kNm}$$

$$\tau_{turbine@289.22MW} = 959.8 \text{ kNm}$$

**Step 03:-**Calculation for excessive mechanical torque through main turbine shaft

While operating the feed pumps without using power which is generated by the main generator, let's consider how 289.22 MW electricity power is generated as generator unit output power. Although the generator produces 289.22 MW, turbine is capable of operating at plant rated operational conditions. Therefore some excessive mechanical torque power can be expected through the main turbine shaft at 300 MW.

$$\text{Available excessive torque} = \tau_{\text{turbine@300MW}} - \tau_{\text{turbine@289.22MW}}$$

$$\text{Available excessive torque} = 997.2 \text{ kNm} - 959.8 \text{ kNm}$$

$$\text{Available excessive torque} = 37.4 \text{ kNm}$$

Hence the rotating speed of whole combine turbine shaft is 3000 rpm;

$$\text{Available excessive mechanical torque power} = \tau_{\text{excessive}} \times 3000 \times \frac{2\pi}{60}$$

$$\text{Available excessive mechanical torque power} = 37.4 \text{ kNm} \times 3000 \times \frac{2\pi}{60}$$

$$\text{Available excessive mechanical torque power} = 11,749 \text{ kW} = 11.75 \text{ MW}$$

➤ Potential of steam sources through four steam extractions

When the plant is operated on rated operational condition (at 300 MW) and the generator produces 289.22 MW power, some excessive steam quantity due to operation of feed pumps with separate alternative power supply can be expected. Therefore it needs to calculate the required steam capacity for turbines and its power potential for each case. Then the available excessive steam potential can be calculated with reference to 300 MW and 289.22 MW.

University of Moratuwa, Sri Lanka  
Electronic Theses & Dissertations  
www.lib.mrt.ac.lk

Power producing ratio of the combined turbine shaft

$$\text{Power ratio } P_{HP} : P_{IP} : P_{LP1} : P_{LP2} = 0.2410 : 0.2712 : 0.2439 : 0.2439$$

Figure 4.4.5: Thrust force distribution and turbine power ratios

Power extraction in a combined turbine rotors is done by different ratios. In designing of the overall rotor combination, it is designed as much as balancing their thrust forces. See the Figure 4.5. Therefore when extracting power through common shaft with combined turbine rotors, all turbines have unique power ratio which is inherited by design. See the Table 4.7 [16].

Table 4.4.7: Power contribution by turbine stages at various loads

| Power ratio<br>( ±5.0% )    | P <sub>HP</sub> | P <sub>IP</sub> | P <sub>LP1</sub> | P <sub>LP2</sub> |
|-----------------------------|-----------------|-----------------|------------------|------------------|
|                             | 0.2410          | 0.2712          | 0.2439           | 0.2439           |
| Power @ 150 MW (Half load)  | 31.15           | 40.68           | 36.58            | 36.58            |
| Power @ 270 MW              | 65.07           | 73.22           | 65.85            | 65.85            |
| Power @ 300 MW (Rated load) | 72.3            | 81.36           | 73.17            | 73.17            |
| Power @ 336 MW (BMCR)       | 80.976          | 91.12           | 81.95            | 81.95            |

Electronic Theses & Dissertations  
www.lib.mrt.ac.lk

**Step 01:-** Calculation for required steam capacities through turbines at 300 MW

- Efficiency of main electric generator<sup>[16]</sup> =  $\eta_{Generator} = 99.25\%$
- Efficiency of HP turbine stage<sup>[16]</sup> =  $\eta_{HP} = 95.25\%$
- Efficiency of IP turbine stage<sup>[16]</sup> =  $\eta_{IP} = 96.9\%$
- Efficiency of LP turbine stages<sup>[16]</sup> =  $\eta_{LP} = 98.8\%$
- Overall efficiency of combined turbine rotor =  $\eta_{Turbine}$

$$\eta_{Turbine} = \eta_{HP} \times \eta_{IP} \times \eta_{LP}$$

$$\eta_{Turbine} = 95.25\% \times 96.9\% \times 98.8\% = 91.19\%$$

$$\begin{aligned} \text{Generator shaft inlet power} &= \frac{300 \text{ MW}}{\eta_{Generator}} = \frac{300 \text{ MW}}{0.9925} = 302.27 \text{ MW} \\ \text{@ rated power} & \end{aligned}$$

$$\begin{aligned}
 \text{Power extraction @300 MW} &= P_{HP@300MW} : P_{IP@300MW} : 2 \times P_{LP@300MW} \\
 &= 302.27 \times 0.2410 : 302.27 \times 0.2712 : 2 \times 302.27 \times 0.2439 \\
 &= 72.85 \text{ MW} : 81.98 \text{ MW} : 147.45 \text{ MW}
 \end{aligned}$$

- Boiler operation conditions @ 300 MW capacity

$$\text{Boiler main steam pressure}^{[16]} = 16.7 \text{ MPa}$$

$$\text{Boiler main steam temperature}^{[16]} = 538 \text{ }^\circ\text{C}$$

- Calculation for required steam capacity through HP turbine

$$P = \dot{m} \times \Delta h \quad ; \text{Where } P \text{ – power in kW}$$

$$\dot{m} \text{ – steam flow rate in kg/s}$$

$$\Delta h \text{ – enthalpy difference in kJ/kg}$$

$$P_{HP@300MW} = \dot{m}_{HP@300MW} \times (h_{1@300MW} - h_{2@300MW})$$

$$\begin{aligned}
 72.85 \times 10^3 \text{ kW} &= \dot{m}_{HP@300MW} \times (3396.9 - 3048.9) \text{ kJ/kg} \\
 \dot{m}_{HP@300MW} &= 211.78 \text{ kg/s} = 762.24 \text{ T/h}
 \end{aligned}$$

- Calculation for required steam capacity through IP turbine

$$P_{IP@300MW} = \dot{m}_{IP@300MW} \times (h_{3@300MW} - h_{4@300MW})$$

$$81.98 \times 10^3 \text{ kW} = \dot{m}_{IP@300MW} \times (3535.9 - 3168.7) \text{ kJ/kg}$$

$$\dot{m}_{IP@300MW} = 223.26 \text{ kg/s} = 803.72 \text{ T/h}$$

- Calculation for required steam capacity through LP turbines

$$2 \times P_{LP@300MW} = \dot{m}_{LP@300MW} \times (h_{5@300MW} - h_{6@300MW})$$

$$147.45 \times 10^3 \text{ kW} = \dot{m}_{LP@300MW} \times (3168.7 - 2368.6) \text{ kJ/kg}$$

$$\dot{m}_{LP@300MW} = 184.29 \text{ kg/s} = 663.44 \text{ T/h}$$

**Step 02:-** Calculation for required steam capacities through turbines at 289.22 MW

$$\begin{aligned} \text{Generator shaft inlet power} &= \frac{289.22 \text{ MW}}{\eta_{\text{Generator}}} = \frac{289.22 \text{ MW}}{0.9925} = 292.19 \text{ MW} \\ @ 289.22 \text{ MW} & \end{aligned}$$

$$\begin{aligned} \text{Power extraction} &= P_{\text{HP@289.22MW}} : P_{\text{IP@289.22MW}} : 2 \times P_{\text{LP@289.22MW}} \\ @ 289.22 \text{ MW} & \\ &= 292.19 \times 0.2410 : 292.19 \times 0.2712 : 2 \times 292.19 \times 0.2439 \\ &= 70.42 \text{ MW} : 79.24 \text{ MW} : 142.53 \text{ MW} \end{aligned}$$

- Boiler operation conditions @ 289.22 MW capacity

$$\text{Boiler main steam pressure}^{[16]} = 16.7 \text{ MPa}$$

$$\text{Boiler main steam temperature}^{[16]} = 538 \text{ }^\circ\text{C}$$

- Calculation for required steam capacity through HP turbine

$$P_{\text{HP@289.22MW}} = \dot{m}_{\text{HP@289.22MW}} \times (h_{1@289.22MW} - h_{2@289.22MW})$$

$$70.42 \times 10^3 \text{ kW} = \dot{m}_{\text{HP@289.22MW}} \times (3396.9 - 3048.9) \text{ kJ/kg}$$

$$\dot{m}_{\text{HP@289.22MW}} = 200.35 \text{ kg/s} = 721.26 \text{ T/h}$$

- Calculation for required steam capacity through IP turbine

$$P_{\text{IP@289.22MW}} = \dot{m}_{\text{IP@289.22MW}} \times (h_{3@289.22MW} - h_{4@289.22MW})$$

$$79.24 \times 10^3 \text{ kW} = \dot{m}_{\text{IP@289.22MW}} \times (3535.9 - 3168.7) \text{ kJ/kg}$$

$$\dot{m}_{\text{IP@289.22MW}} = 210.79 \text{ kg/s} = 758.84 \text{ T/h}$$

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
[www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

- Calculation for required steam capacity through LP turbines

$$2 \times P_{LP@289.22MW} = \dot{m}_{LP@289.22MW} \times (h_{5@289.22MW} - h_{6@289.22MW})$$

$$142.53 \times 10^3 \text{ kW} = \dot{m}_{LP@289.22MW} \times (3168.7 - 2368.6) \text{ kJ/kg}$$

$$\dot{m}_{LP@289.22MW} = 178.14 \text{ kg/s} = 641.3 \text{ T/h}$$

**Step 03:-** Calculation for excessive steam capacities through turbines

$$\text{Excessive steam capacities through a turbine} = \dot{m}_{@300MW} - \dot{m}_{@289.22MW}$$

$$\therefore \text{Excessive steam capacities through HP turbine} = \dot{m}_{\text{Ex.steam@HP}}$$

$$\dot{m}_{\text{Ex.steam@HP}} = \dot{m}_{\text{HP@300MW}} - \dot{m}_{\text{HP@289.22MW}}$$

$$\dot{m}_{\text{Ex.steam@HP}} = (211.78 - 200.35) \text{ kg/s}$$

$$\dot{m}_{\text{Ex.steam@HP}} = 11.43 \text{ kg/s}$$

$$\therefore \text{Excessive steam capacities through IP turbine} = \dot{m}_{\text{Ex.steam@IP}}$$

University of Moratuwa, Sri Lanka  
Electronic Theses & Dissertations

www.lib.mrt.ac.lk

$$\dot{m}_{\text{Ex.steam@IP}} = \dot{m}_{\text{IP@300MW}} - \dot{m}_{\text{IP@289.22MW}}$$

$$\dot{m}_{\text{Ex.steam@IP}} = (223.26 - 210.79) \text{ kg/s}$$

$$\dot{m}_{\text{Ex.steam@IP}} = 12.74 \text{ kg/s}$$

$$\therefore \text{Excessive steam capacities through LP turbines} = \dot{m}_{\text{Ex.steam@LP}}$$

$$\dot{m}_{\text{Ex.steam@LP}} = \dot{m}_{\text{LP@300MW}} - \dot{m}_{\text{LP@289.22MW}}$$

$$\dot{m}_{\text{Ex.steam@LP}} = (184.29 - 178.14) \text{ kg/s}$$

$$\dot{m}_{\text{Ex.steam@LP}} = 6.15 \text{ kg/s}$$

**Step 04:-** Calculation for power potential of steam sources

Table 4.4.8 : Calculation summary of power potential for steam sources

| Steam source                      | Excessive steam capacity (kg/s) | Enthalpy of source (kJ/kg) | Enthalpy of discharge condition* (kJ/kg) | Power potential of the source(MW)<br>$P = \dot{m} \times \Delta h$ |
|-----------------------------------|---------------------------------|----------------------------|--|--|
| Extraction -1<br>(Inlet of HPT)   | 11.43                           | 3396.9                     | 2368.6                                   | 11.75  |

\*Assume the steam discharge condition is equal to condenser condition

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
[www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

➤ Wind power potential associated to the site of NCPP

Wind turbine details of some wind power farms which are operated in Norochcholai area are mentioned in the Table 4.9 [56].

Table 4.4.9 : Wind turbine details of some wind power farms in Norochcholai

| Wind farm         | Made                | Capacity (MW) | Hub height (m) | Rotor diameter (m) |
|-------------------|---------------------|---------------|----------------|--------------------|
| Daily Life Energy | Re-Gen<br>(Germany) | 1.5           | 85             | 82                 |
| Nirmalapura       | Re-Gen<br>(Germany) | 1.5           | 88             | 80                 |
| PowerGen          | LiteWind            | 1.25          | 65             | 77                 |

As discussed in literature review, longitudinal gap and transverse gap in between tow wind turbine is very important when installing several wind turbines in a wind farm. As a standard, required longitudinal gap and transverse gap are as below [56].

- Longitudinal gap  $\geq 2.5 \times$  Rotor diameter
- Transverse gap  $\geq 10 \times$  Rotor diameter

Assume that the wind turbine type which is used in “Daily Life Energy” wind farm is selected for calculation of site available power potential applicable to Norochcholai power plant;

$$\text{Longitudinal gap between 2 wind turbines} = 2.5 \times 82 \text{ m} = 205 \text{ m}$$

$$\text{Transverse gap between 2 wind turbines} = 10 \times 82 \text{ m} = 820 \text{ m}$$

According to the dimensions of the site in Norochcholai power plant, most suitable placement of these wind turbines are marked in Figure 4.6. Eleven numbers of wind turbines can be installed as fulfilled gap requirements.

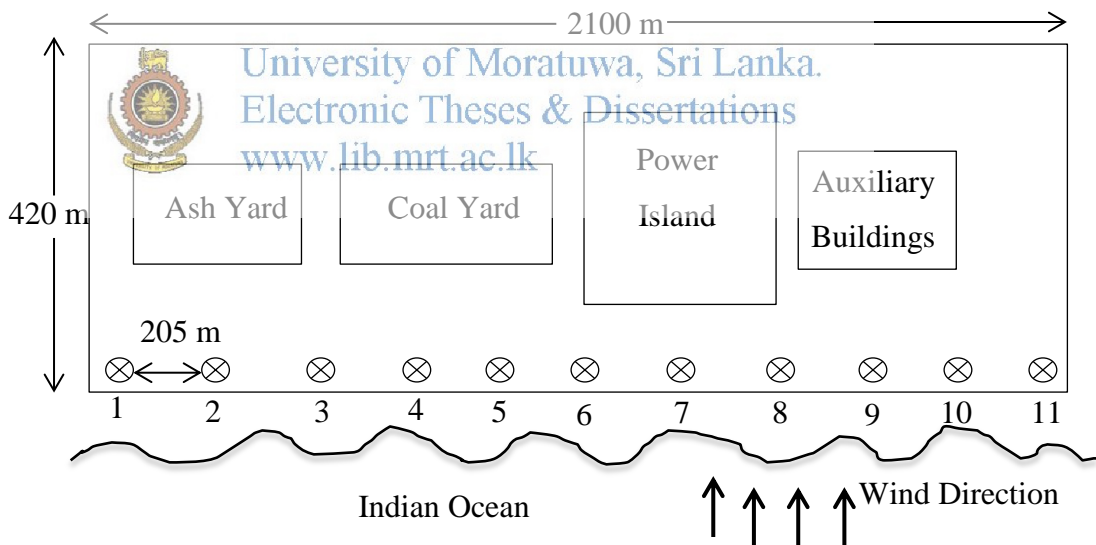

Figure 4.4.6 : Placement of wind turbine in site of Norochcholai power plant

➤ Power potential of sea wave associated to the site of NCPP

According literature review, energy density of sea waves is depended on depth of the sea [40]. See Figure 4.7.

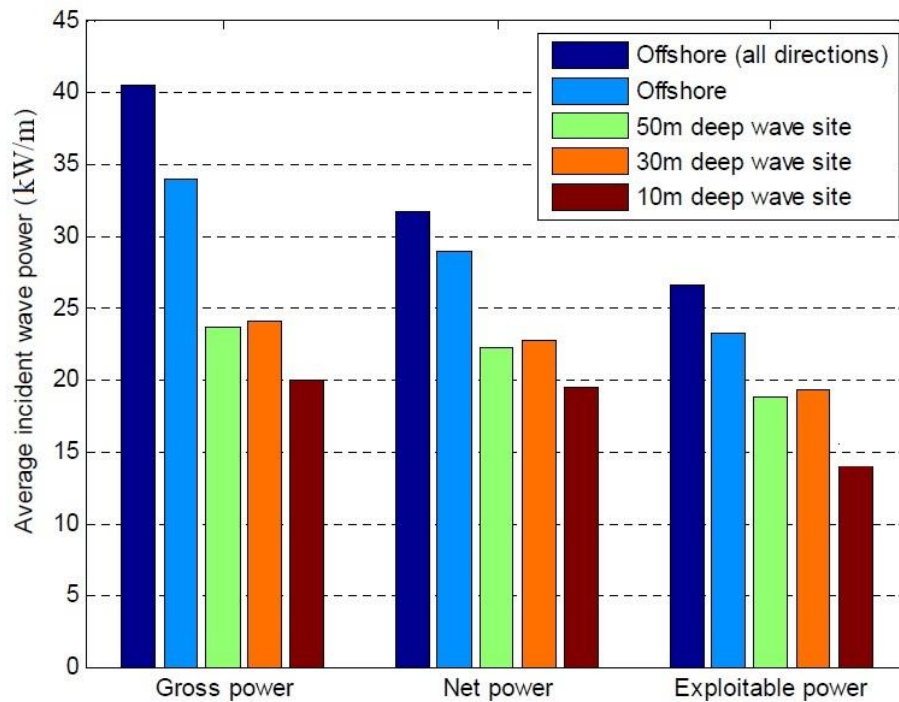

Figure 4.4.7 : Power potential variation with depth of the shore

Source: <http://www.aquamarinepower.com/sites/resources>

University of Moratuwa, Sri Lanka.

Electronic Theses & Dissertations

- Sea depth near the Norochcholai power plant is varying from 8 m to 12 m [57]. As an average, 10 m depth can be expected in the sea near the power plant.

$$\therefore \text{Exploitable power @ 10m depth}^{[41]} = 13.5 \text{ kW/m}$$

- Length of the shore facing to Norochcholai site is 2100 m [50].

$$\therefore \text{Exploitable power near the Norochcholai site} = 13.5 \text{ kW/m} \times 2100 \text{ m}$$

$$\therefore \text{Exploitable power near the Norochcholai site} = 28,350 \text{ kW} = 28.35 \text{ MW}$$

- Optimal overall efficiency of existing wave power mechanisms is nearly 35% [47].

$$\therefore \text{Site available wave power potential} = 28.35 \text{ MW} \times \frac{35}{100} = 9.92 \text{ MW}$$

➤ Power potential of sea wave associated to the site of NCPP

Figure 4.4.8 : Building utilisation in site of Norochcholai power plant

- Effective area for installation of solar collectors =  $A_{Total} - A_1 - A_2 - A_3 - A_4$   
 $= 882,000 \text{ m}^2 - 135,000 \text{ m}^2 - 180,000 \text{ m}^2 - 105,000 \text{ m}^2 - 90,000 \text{ m}^2$

University of Moratuwa, Sri Lanka.  
 Electronic Theses & Dissertations  
[www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

➤ Most suitable solar energy extraction method for locations which are not fully bared as well as area less than  $1 \text{ km}^2$  is tilted photovoltaic cells system. Other methods are comparatively required huge area [48].

- Solar potential at latitude<sup>[44]</sup> =  $5.5 - 6.0 \text{ kWhr} / \frac{\text{m}^2}{\text{day}} = 0.23 - 0.25 \text{ kW} / \text{m}^2$

$$\begin{aligned} \text{Average solar potential} &= \frac{0.2 + 0.25 \text{ kW} / \text{m}^2}{2} = 0.24 \text{ kW} / \text{m}^2 \\ &= 89,280 \text{ kW} = 89.28 \text{ MW} \end{aligned}$$

- Although the general efficiency of photovoltaic cells is around 10% to 12%, it can be increased up to 15% by using solar tracking mechanism [48].

$$\begin{aligned} \therefore \text{Site available solar} & \\ \text{power potential} &= 89.28 \text{ MW} \times \frac{15}{100} = 13.39 \text{ MW} \end{aligned}$$

#### 4.4.6 Existing power demand of BFP motor in NCPP

- According to the equipment design description, power capacity of 4.87 MW is consumed by 1 BFP at plant rated power condition [13].
- Efficiency of variable speed fluid coupler is 94.1% [14].

Required power for BFP = 4.87 MW

$$\begin{aligned} \text{Power demand by BFP motor} &= \frac{\text{Required power for BFP}}{\text{Efficiency of fluid coupler}} \times 100 \\ &= \frac{4.87 \text{ MW}}{94.1} \times 100 = 5.28 \text{ MW} \end{aligned}$$

#### 4.4.7 Equivalent power potential of alternatives to BFP's operation

- Required equivalent power for mechanical power source

Due to using of mechanical linkage to power transfer, it is not possible to calculate the equivalent requirement for mechanical power sources in Norochcholai power plant.

- Required power for BFPs through superheated steam sources

- General equipment arrangement of this method is shown in Figure 4.9.

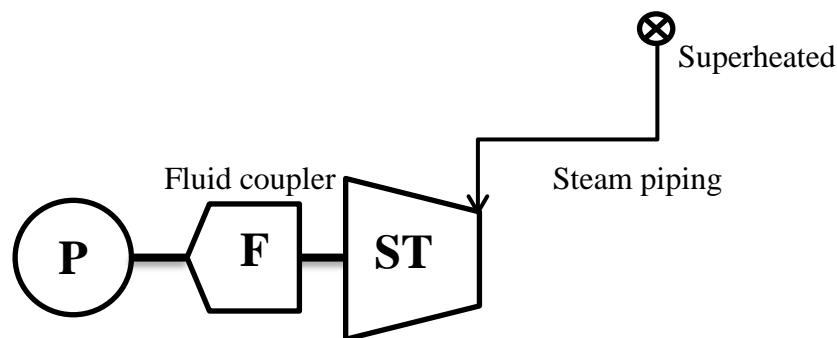

Figure 4.4.9 : Equipment arrangement for BFP operation with steam source

- Industrially available 5 MW turbines and their characteristics are shown in Table 4.10.

Table 4.4.10 : 5 MW turbine and characteristics which are used in industry

| Manufacture  | Inlet Condition |     |        |             |     |      | Efficiency( $\eta$ ) |
|--------------|-----------------|-----|--------|-------------|-----|------|----------------------|
|              | Pressure        |     | Unit   | Temperature |     | Unit |                      |
|              | From            | To  |        | From        | To  |      |                      |
| Kawasaki[23] | 31              | 81  | bar(a) |             |     |      | 87.5%                |
| Kessels [23] | 32              | 65  | bar(a) | 380         | 440 | C    | 84%                  |
|              | 19.5            | 21  | bar(a) | -           | 336 | C    | 90.8%                |
| Siemens [63] | -               | 131 | bar(a) | -           | 530 | C    | 96.3%                |
| Marc [23]    |                 | 90  | bar(a) |             | 500 | C    | 93.5%                |
| GE[65]       |                 | 170 | bar(a) |             | 565 | C    | 97.8%                |

- Distance from steam tapping points (under main turbine casing) to boiler feed pump is nearly 35 m. See the drawing (F-5222S-J0201-06) in appendix C.
- If small turbine which is manufactured by General Electric Company is selected as prime mover of feed pump, efficiency of steam turbine is 97.8%. (See Table 4.10)

$$\text{Required power @ inlet of steam turbine} = \frac{\text{Required power for Fluid coupler}}{\text{Efficiency of steam turbine}} \times 100$$

$$= \frac{5.28 \text{ MW}}{97.8} \times 100 = 5.4 \text{ MW}$$

**Step 01:-** Calculation for required power when using a steam turbine with steam source #1

$$\begin{aligned} \text{Required steam rate from source \#1} &= \frac{\text{Required power @ inlet of steam turbine}}{(h_{@source\#1} - h_{@Condenser inlet})} \\ &= \frac{5.4 \times 10^3 \text{ kW}}{(3396.9 - 2368.6) \text{ kJ/kg}} \\ &= 5.25 \text{ kg/s} = 18900 \text{ kg/hr} \end{aligned}$$

**Pipe Sizing by Pressure Loss for Steam**

Units: SI(bar)

Figure 4.4.10 : Inputs & results for pipe sizing by pressure loss for source #1

- TLV Company in Kakogawa City, Japan has provided a facility for designing pipe and duct system by using engineering calculator [58]. Calculation for pipe sizing by pressure loss is done using TLV engineering calculator and relevant inputs and results are shown in Figure 4.10.
- Pressure loss in steam pipe is 1.19 bars and equivalent power loss is calculated as below.

$$\begin{aligned} \text{Steam pressure @ turbine inlet} &= \text{Source pressure} - \text{pressure loss in pipe} \\ &= 167 \text{ bar} - 1.19 \text{ bar} \\ &= 165.81 \text{ bar} = 16.58 \text{ MPa} \end{aligned}$$

$$\begin{aligned} \text{Equivalent power loss in pipe} &= \dot{m}_{@ \text{source}\#1} \times (h_{@16.58\text{MPa},538^\circ\text{C}} - h_{@16.7\text{MPa},538^\circ\text{C}}) \\ &= 5.25 \text{ kg/s} \times (3398.28 - 3396.9) \text{ kJ/kg} \\ &= 7.25 \text{ kW} = 0.007 \text{ MW} \end{aligned}$$

$$\therefore \text{Required power for 1 BFP @ source \#1} = 5.4 \text{ MW} + .007 \text{ MW}$$

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
www.lib.mrt.ac.lk

$$\therefore \text{Required power for 2 BFPs @ source \#1} = 5.407 \text{ MW} \times 2 = 10.814 \text{ MW}$$

**Step 02:-** Calculation for required power when using a steam turbine with steam source #2

$$\begin{aligned} \text{Required steam rate from source \#2} &= \frac{\text{Required power @ inlet of turbine}}{(h_{@ \text{source}\#2} - h_{@ \text{condenser inlet}})} \\ &= \frac{5.4 \times 10^3 \text{ kW}}{(3048.9 - 2368.6) \text{ kJ/kg}} \\ &= 7.94 \text{ kg/s} = 28584 \text{ kg/hr} \end{aligned}$$

- Calculation for pipe sizing by pressure loss is done using TLV engineering calculator and relevant inputs and results are shown in Figure 4.11.

### Pipe Sizing by Pressure Loss for Steam

[Hide Advanced Options](#)

**Result**

|                                    |         |       |
|------------------------------------|---------|-------|
| Pipe Size                          | DN150   |       |
| Pipe Inner Diameter                | 159.3   | mm ▼  |
| Steam Velocity                     | 25.1655 | m/s ▼ |
| Pressure Loss                      | 1.67451 | bar ▼ |
| Equivalent Length of Straight Pipe | 345.416 | m ▼   |

Figure 4.4.11 : Inputs & results for pipe sizing by pressure loss for source #2

- Pressure loss in steam pipe is 1.67 bars and equivalent power loss is calculated as bellow.

$$\begin{aligned}
 \text{Steam pressure @ turbine inlet} &= \text{Source pressure} - \text{pressure loss in pipe} \\
 &= (39.3 \text{ bar} - 1.67 \text{ bar}) = 37.63 \text{ bar} \\
 &= 3.76 \text{ MPa}
 \end{aligned}$$

$$\begin{aligned}
 \text{Equivalent power loss in pipe} &= \dot{m}_{@ \text{source}\#2} \times (h_{@3.76\text{MPa},331.2^\circ\text{C}} - h_{@3.93\text{MPa},331.2^\circ\text{C}}) \\
 &= 7.94 \text{ kg/s} \times (3053.33 - 3048.9) \text{ kJ/kg} \\
 &= 35.17 \text{ kW} = 0.035 \text{ MW}
 \end{aligned}$$

$$\therefore \text{Required power for 1 BFP @ source \#2} = (5.4 \text{ MW} + .035 \text{ MW}) = 5.435 \text{ MW}$$

$$\therefore \text{Required power for 2 BFPs @ source \#2} = 5.435 \text{ MW} \times 2 = 10.87 \text{ MW}$$

**Step 03:-** Calculation for required power when using a steam turbine with steam source #3

$$\begin{aligned} \text{Required steam rate from source \#3} &= \frac{\text{Required power @ inlet of turbine}}{(h_{\text{source\#3}} - h_{\text{condenser inlet}})} \\ &= \frac{5.4 \times 10^3 \text{ kW}}{(3535.9 - 2368.6) \text{ kJ/kg}} \\ &= 4.63 \text{ kg/s} = 16668 \text{ kg/hr} \end{aligned}$$

- Calculation for pipe sizing by pressure loss is done using TLV engineering calculator and relevant inputs and results are shown in Figure 4.12.

| Equivalent Length of Straight Pipe | 454.371 | m   | ▼ |

Figure 4.4.13 : Inputs & results for pipe sizing by pressure loss for source #4

- Pressure loss in steam pipe is 1.75 bars and equivalent power loss is calculated as bellow.

$$\begin{aligned}
 \text{Steam pressure @ turbine inlet} &= \text{Source pressure} - \text{pressure loss in pipe} \\
 &= 9.57 \text{ bar} - 1.75 \text{ bar} \\
 &= 7.82 \text{ bar} = 0.782 \text{ MPa}
 \end{aligned}$$

$$\begin{aligned}
 \text{Equivalent power loss in pipe} &= \dot{m}_{@ \text{ source\#4}} \times (h_{@0.782\text{MPa},354^\circ\text{C}} - h_{@0.957\text{MPa},354^\circ\text{C}}) \\
 &= 6.75 \text{ kg/s} \times (3172.13 - 3168.7) \text{ kJ/kg}
 \end{aligned}$$

$$\therefore \text{Required power for 1 BFP @ source \#4} = (5.4 \text{ MW} + .023 \text{ MW}) = 5.423 \text{ MW}$$

$$\therefore \text{Required power for 2 BFP @ source \#4} = 5.423 \text{ MW} \times 2 = 10.85 \text{ MW}$$

**Step 05:-** Summarisation for equivalent required power potential when using steam source with a steam turbine and steam piping

Table 4.4.11 : Required power for operation of 2BFPs from each source point

| Superheated steam source             | Required power for 2 BFP from source (MW) |
|--------------------------------------|---|
| Extraction -1 (Inlet of HP turbine)  | 10.81                                     |
| Extraction -2 (Cold Re-heater)       | 10.87                                     |
| Extraction -2 (Hot Re-heater)        | 10.82                                     |
| Extraction -2 (Outlet of IP turbine) | 10.85                                     |

- Required equivalent power potential for BFP operation through wind power
- Between the two ways of power transferring, mechanical power extraction mechanisms are difficult to implement for the existing power plant due disturbance of structures and equipment. Therefore the most suitable way is transferring power through conductors.
  - Equipment arrangement of this method is shown in Figure 4.14.

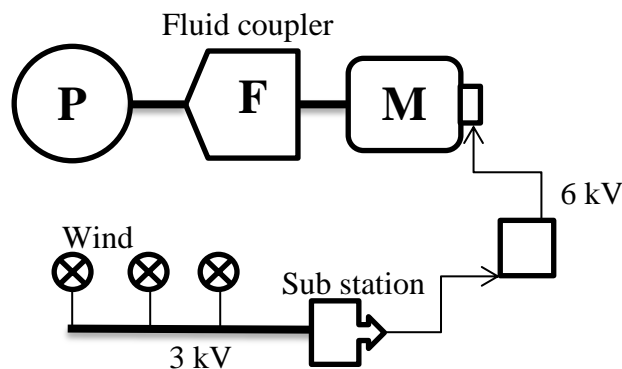

Figure 4.4.14 : Equipment arrangement for BFP operation with wind source

- Efficiency of motor of BFP in NCPP is 98% [13].
- Efficiency of step-up transformer is 98.7% [13].

$$\therefore \text{Required power for motor} = \frac{\text{Required power for Fluid coupler}}{\text{Efficiency of motor}} \times 100$$

$$\text{Required power for motor} = \frac{5.28 \text{ MW}}{98} \times 100 = 5.39 \text{ MW}$$

- Most appropriate place for substation near the 7<sup>th</sup> wind tower which is mentioned in Figure 4.6 due to closeness to the power island.
  - By using online electric loss calculator which is facilitated by Photovoltaic & solar electricity design company, power losses from wind turbines to transformer as well as power losses from transformer to motor can be calculated [60].
- ✓ If the wind turbine type which is used in “Daily Life Energy” wind farm is selected, output parameters of generator are shown in Table 4.12.

Table 4.4.12 : Output parameter for generator of Re-Gen wind turbine

| Parameter         | Value      | Unit |
|-------------------|------------|------|
| Power supply type | 3 phase AC | --   |
| Voltage           | 3000       | V    |
| Current           | 340        | A    |
| Power factor      | 0.85       | --   |
| Power             | 1500000    | W    |

- ✓ Parameters of supplied power for motor of BFP are shown in Table 4.13.

Table 4.4.13 : Parameter of supplied power to BFP motors in Norochcholai

| Parameter         | Value      | Unit |
|-------------------|------------|------|
| Power supply type | 3 phase AC | --   |
| Voltage           | 6000       | V    |
| Current           | 610        | A    |
| Power factor      | 0.85       | --   |
| Power             | 5390000    | W    |

- ✓ Required length of cables from substation to motor is nearly 500 m. See Figure 4.6.

- ✓ Armed 3 core copper cables with 400 mm<sup>2</sup> are selected [61].

**Step 01:-** Calculation for power losses from motor to transformer

**AC LOSSES CALCULATOR**

| AC POWER                 | AC Voltage Drop                   | AC Energy losses              |
|--------------------------|-----------------------------------|-------------------------------|
| Three-phase              | wire material : Copper            | AC Energy losses : 32093.63 W |
| Voltage (U): 6000 V      | Wire size (mm <sup>2</sup> ): 400 | AC Energy losses (%): 0.60 %  |
| AC Current (Ib): 610 A   | Simple length (one run) : 500 m   | calculate                     |
| Power factor (PF): 0.85  | AC Drop voltage : 27.76 V         |                               |
| AC POWER (P) : 5388252 W | AC Drop voltage (%): 0.80         |                               |
| calculate                | calculate                         |                               |

Figure 4.4.15 : Screen shot of loss calculator for cabling from motor to TF

Calculation for power losses from motor to transformer is done using electric loss calculator [60] and relevant inputs and results are shown in Figure 4.15.

$$\therefore \text{Power losses from motor to transformer} = 32093.63 \text{ W} = 0.032 \text{ MW}$$

**Step 02:-** Calculation for power losses through the transformer

$$\begin{aligned} \text{Power losses @ transformer} &= \text{Operating power through TF} \times \frac{(100 - \eta_{TF})}{100} \\ &= (5.39 \text{ MW} + 0.032 \text{ MW}) \times \frac{(100 - 98.7)}{100} \\ &= 5.42 \text{ MW} \times 0.013 = 0.07 \text{ MW} \end{aligned}$$

**Step 03:-** Calculation for power losses from transformer to wind turbines

Required length of cables, cable size and calculated percentages of power losses from each wind turbines to substation are summarised in Table 4.14. Estimating the cable lengths is done base on Figure 4.6 and relevant power losses are calculated using electric loss calculator [60].

Table 4.4.14 : Summary of cable details and percentage losses from TF to WTB

| Wind turbine | Required cable length (m) | Cable size (mm <sup>2</sup> )* | Percentage of power loss (%)** |
|--------------|---------------------------|--------------------------------|--------------------------------|
| 1            | 1280                      | 300                            | 2.27                           |
| 2            | 1075                      | 240                            | 2.38                           |
| 3            | 870                       | 150                            | 3.08                           |
| 4            | 665                       | 120                            | 2.94                           |
| 5            | 460                       | 120                            | 2.04                           |
| 6            | 255                       | 120                            | 1.13                           |

| Wind turbine | Required cable length (m) | Cable size (mm <sup>2</sup> )* | Percentage of power loss (%)** |
|--------------|---------------------------|--------------------------------|--------------------------------|
| 7            | 50                        | 120                            | 0.22                           |
| 8            | 255                       | 120                            | 1.13                           |
| 9            | 460                       | 120                            | 2.04                           |
| 10           | 665                       | 120                            | 2.94                           |
| 11           | 870                       | 150                            | 3.08                           |

\*Armed 3 core copper cables are selected[61]

\*\* Electric loss calculator [60]

$$\text{Transformer power input} = 5.42 \text{ MW} + 0.07 \text{ MW} = 5.5 \text{ MW}$$

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
[www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

- Assume that the 5.42 MW is equally given by 11 wind towers.

$$\text{Power supply to transformer by 1 wind turbine} = \frac{5.5 \text{ MW}}{11} = 0.5 \text{ MW}$$

- Power losses from transformer to each wind turbines are calculated using electric loss calculator and calculated power losses are summarised in Table 4.15.

Table 4.4.15 : Summary of losses in each cable from TF to WTB

| Wind turbine    | 1    | 2    | 3    | 4    | 5    | 6    | 7 | 8    | 9    | 10   | 11   | Total |
|-----------------|------|------|------|------|------|------|---|------|------|------|------|-------|
| Power Loss (MW) | 0.03 | 0.04 | 0.05 | 0.04 | 0.03 | 0.02 | 0 | 0.02 | 0.03 | 0.04 | 0.05 | 0.35  |

$\therefore$  Power losses from motor to transformer = 0.35 MW

- Required power for 1 BFP by wind turbines =  $(5.39 + 0.032 + 0.07 + 0.35)MW$   
= 5.84 MW
- Required power for 2 BFP by wind turbines =  $5.84 MW \times 2 = 11.68 MW$

- Required equivalent power potential for BFPs through sea wave energy
  - Energy transferring ways are almost same to the application which is used for energy transferring in wind power sources.
  - As usual, mechanical power extraction mechanisms are difficult to implement for existing power plant due disturbance of structures and equipment. Except cabling from generator of sea wave energy extractor to transformer, all other equipment and cable selections are equal to previous case.
  - Assume that the output voltage of generator is stepped-up directly to 6 KV.
  - Equipment arrangement of this method is shown in Figure 4.16.

Figure 4.4.16 : Equipment arrangement for BFP operation with Sea wave energy

Required power for 1 BFP from sea waves =  $(5.39 + 0.032 + 0.07)MW$   
= 5.5 MW

$\therefore$  Required power for 2 BFP from sea waves =  $5.5 MW \times 2 = 11 MW$

➤ Required equivalent power potential for BFP operation through solar energy

Figure 4.4.17 : Equipment arrangement for BFP operation with solar power

In this mechanism, all equipment from BFP to transformer is almost similar to the previously discussed equipment arrangement. Therefore 5.5 MW power can be taken as the input requirement for the transformer. The general equipment arrangement of this method is shown in Figure 4.17.

- Efficiency of DC to AC converter is 97.5% [48]

$$\text{Power loss @ inverter} = \text{supply power to TF} \times \frac{(100 - \eta_{\text{Inverter}})}{100}$$

$$= 5.5 \text{ MW} \times \frac{(100 - 97.5)}{100} = 0.14 \text{ MW}$$

$$\begin{aligned} \text{Required power for 1 BFP from solar source} &= 5.5 \text{ MW} + 0.14 \text{ MW} \\ &= 5.64 \text{ MW} \end{aligned}$$

$$\therefore \text{Required power for 2 BFP from solar source} = 5.64 \text{ MW} \times 2 = 11.28 \text{ MW}$$

#### 4.4.8 Satisfaction of BFP power requirement

Table 4.4.16 : Summary of BFP power satisfaction in NCPP

| Power source               | Site available power potential (MW) | Required power potential for BFP (MW) | Satisfactory Level |            |
|----------------------------|-------------------------------------|---------------------------------------|--------------------|------------|
| Mechanical Power sources   | 11.75                               | ----                                  | ----               |            |
| Super-heated steam sources | Extraction -1                       | 11.75                                 | 10.814             | Satisfied  |
|                            | Extraction -2                       | 7.78                                  | 10.87              | Not enough |
|                            | Extraction -3                       | 14.88                                 | 10.82              | Satisfied  |
|                            | Extraction -4                       | 5.21                                  | 10.85              | Not enough |
| Wind power source          | 16.5                                | 11.68                                 | Satisfied          |            |
| Sea waves                  | 9.92                                | 11                                    | Not enough         |            |
| Solar power                | 13.39                               | 11.28                                 | Satisfied          |            |

#### 4.4.9 Implementation cost related to the alternatives in NCPP

##### ➤ Implementation cost for mechanical source

Due to using of mechanical linkage to power transfer, it is extremely difficult to transfer power. It needs total design change on MPB in NCPP. Therefore implementation cost mechanical sources are not estimated.

##### ➤ Implementation cost for superheated steam sources

- Details of selected steam turbine.

If the SST-060 steam turbine of AFA series which is manufactured by Siemens Power Company is selected as the prime moving steam turbines for Norochcholai

coal power plant, relevant technical specifications of the pump are mention in Table 4.17 [63].

Table 4.4.17 : Technical specifications of SST-060 ST by Siemens

| Specification               | Value       | Unit |
|-----------------------------|-------------|------|
| Type                        | Compact set |      |
| Length                      | 2.5         | m    |
| Width                       | 1.5         | m    |
| Height                      | 2.5         | m    |
| Overall weight              | 22.4        | T    |
| Max. power output           | 6           | MW   |
| Operating pressure range    | 13.1-17     | MPa  |
| Operating temperature range | 530-548     | °C   |

**Step 01:** - Cost calculation for new basements

- Applied load for the basement is approximately 22.5 T
- Required detentions for basement = 2.75 m X 1.75 m X 0.9 m with premix concrete class S3-122 and reinforcement class EN 10138-4 [68].
- Cost for class S3-122 premixed concrete = 43,875 US\$/m<sup>3</sup> [64].
- Cost for reinforcement class EN 10138-4 = 60,000 US\$/m<sup>3</sup> [64].

$$\text{Volume of basement} = 2.75 \text{ m} \times 1.75 \text{ m} \times 0.9 \text{ m} = 4.33 \text{ m}^3$$

$$\therefore \text{Cost for premixed concrete} = 4.33 \text{ m}^3 \times 43,875 \text{ US\$/m}^3$$

$$= \text{US\$ } 0.19 \text{ M}$$

$$\therefore \text{Cost for reinforcement} = 4.33 \text{ m}^3 \times 60,000 \text{ US\$/m}^3$$

$$= \text{US\$ } 0.26 \text{ M}$$

$$\text{Total cost for 1 basement} = \text{US\$ } 0.19 \text{ M} + \text{US\$ } 0.26 \text{ M}$$

$$= \text{US\$ } 0.45 \text{ M}$$

**Step 02:** - Cost calculation for new equipments

- Approximate cost for 5 MW steam turbine set is US\$ 1,000,000 [65].  
 $\therefore \text{Cost for } 2 \times 5 \text{ MW steam turbines} = \text{US\$ } 1,000,000 \times 2 = \text{US\$ } 2\text{M}$
- According to the technical agreement of 3X300 MW Puttalam coal power project, cost estimation of steam and water piping is given per meter length. This cost figures are included cost of pipe material, cost of pipe component (bends, valves, drains and air vents etc.), cost of pipe hangers and supports as well as the cost of the thermal insulation materials. Details of cost estimation for steam and water piping are shown in the Table 4.18 [64].

Table 4.18 : Cost estimation details for steam and water piping in PCPP

www.lib.mrt.ac.lk

| Item/Pipe              | Unit cost (US\$/m) | Units (m) | Total cost (US\$ M) |
|------------------------|--------------------|-----------|---------------------|
| Main steam             | 52,480             | 108       | 5.66                |
| Hot re-heater steam    | 58,750             | 120       | 7.05                |
| Cold re-heater steam   | 62,300             | 94.5      | 5.88                |
| HP bypass steam        | 42,450             | 12        | 0.50                |
| HP/HT extraction steam | 27,715             | 155       | 4.29                |
| LP/LT extraction steam | 19,650             | 270       | 5.30                |

| Item/Pipe             | Unit cost (US\$/m) | Units (m) | Total cost (US\$ M) |
|-----------------------|--------------------|-----------|---------------------|
| LP bypass steam       | 34,350             | 23.2      | 0.79                |
| Gland sealing steam   | 08,500             | 335       | 2.84                |
| Auxiliary steam       | 13,255             | 415       | 5.50                |
| Feed water            | 45,510             | 278       | 12.65               |
| De-superheating spray | 06,700             | 390       | 2.61                |
| Condensate water      | 32,665             | 315       | 10.28               |

All identified steam sources are extracted through same high pressure and high temperature extractions which are used to heat up regenerative heaters. Therefore the condition of extracted steam for new steam turbine is almost equal to the conditions which are supplied to the regenerative heaters. Based on this circumstance, cost of new steam piping is assumed that similar to rates of cost of HP/HT extraction piping.

$$\therefore \text{Cost for steam piping} = \text{Length of pipe}^{[66]} \times \text{Unit cost rate}$$

$$\text{Cost for steam piping} = 2 \times 35 \text{ m} \times 27,715 \text{ US\$/m} = \text{US\$ } 1.94 \text{ M}$$

$$\therefore \text{Total implementation cost} = 2 \times C_{\text{Basement}} + 2 \times C_{\text{ST}} + 2 \times C_{\text{Steam piping}}$$

$$\begin{aligned} \text{Total implem. cost for steam sources} &= \text{US\$ } 0.89 \text{ M} + \text{US\$ } 2 \text{ M} + \text{US\$ } 1.94 \text{ M} \\ &= \text{US\$ } 4.83 \text{ M} \end{aligned}$$

➤ Implementation cost for wind energy sources

**Step 01:** - Cost estimation for set of complete wind turbine

For collection easiness of cost data, equipment and installation cost for complete set of wind turbine can be considered as lump cost. Because there are many wind

farms have been installed in Norochcholai area and easily these cost can be found out through their project reports.

- WindForce Energy private limited has 5 wind farms around Norochcholai area and cost for wind turbines for each wind farms are shown in Table 4.19.

Table 4.4.19 : Cost details of turbines in wind farms around Norochcholai

| Wind frame        | Turbine capacity(MW) | Numbers of turbines | Cost for wind turbines as lump (US\$) | Cost for 1 turbine (US\$) |
|-------------------|----------------------|---------------------|---------------------------------------|---------------------------|
| Daily Life Energy | 1.5                  | 8                   | 25.000 MM                             | 3.125 MM                  |
| Nirmalapura       | 1.5                  | 7                   | 21.875 MM                             | 3.125 MM                  |
| PowerGen          | 1.25                 | 7                   | 18.228 MM                             | 2.604 MM                  |
| Seguwantivu       | 0.8                  | 12                  | 20.004 MM                             | 1.667 MM                  |
| Vidatamunai       | 0.8                  | 13                  | 22.087 MM                             | 1.699 MM                  |

Source: Project cost forecasting report, 2013, WindForce Energy (Pvt) Limited, Sri Lanka

$\therefore$  Required power for 2BFPS from wind turbines = 11.68 MW

- If the wind turbine type which is used in “Daily Life Energy” wind farm is selected,

$$\text{Required numbers of wind turbines} = \frac{11.68 \text{ MW}}{1.5 \text{ MW}} = 7.78 \approx 8$$

$$\therefore \text{Lump cost for wind turbines} = \text{US\$ } 3.125 \text{ M} \times 8$$

$$= \text{US\$ } 25 \text{ M}$$

**Step 02:** - Cost for 12.5 MW / 6 kV step-up transformer

- Approximate cost for 12.5 MW / 6 kV step-up transformer is US\$ 950,000 [65].

**Step 03:** - Cost for Cabling from transformer to wind turbines

- According to the agreement of 3X300 MW Puttalam coal power project, cost estimation of armed 3 core power cabling is scheduled per meter length. This cost figures are included cost of cable, cost of electric auxiliary equipment (cable lug and isolators etc.), and cost of cable laying. Details of cost estimation for power cabling are shown in the Table 4.20 [64].

Table 4.4.20 : Cost estimation details for power cabling - PCPP

| Cable Size<br>(mm <sup>2</sup> ) | Power cabling cost (US\$/m) |                  |
|----------------------------------|-----------------------------|------------------|
|                                  | With cable trenches         | With cable trays |
| 95                               | 192.3                       | 189.5            |
| 120                              | 244.6                       | 239.8            |
| 150                              | 310.2                       | 299.7            |
| 185                              | 388.7                       | 370.2            |
| 240                              | 513.2                       | 480.5            |
| 300                              | 652.8                       | 600.0            |
| 400                              | 896.0                       | 800.0            |

- As per the previous calculation 8 numbers of wind turbines are required to supply 11.68 MW.
- Assume the cable trays are used to lay cables
- Location selection for wind turbines related to the Figure 4.6 and power cabling cost from wind turbines to transformer are calculated and summarised in the Table 4.21.

Table 4.4.21 : Summary of the cost for power cabling from WTB to TF

| Turbine                              | Turbine Location | Cable size (mm <sup>2</sup> ) | Length of cable (m) | Unit cost for cabling (US\$/m) | Cabling cost (US\$) |
|--------------------------------------|------------------|-------------------------------|---------------------|--------------------------------|---------------------|
| 1                                    | #3               | 150                           | 870                 | 299.7                          | 260,782             |
| 2                                    | #4               | 120                           | 665                 | 239.8                          | 159,466             |
| 3                                    | #5               | 120                           | 460                 | 239.8                          | 110,307             |
| 4                                    | #6               | 120                           | 255                 | 239.8                          | 61,149              |
| 5                                    | #7               | 120                           | 050                 | 239.8                          | 11,990              |
| 6                                    | #8               | 120                           | 255                 | 239.8                          | 61,149              |
| 7                                    | #9               | 120                           | 460                 | 239.8                          | 11,0307             |
| 8                                    | #10              | 120                           | 665                 | 239.8                          | 15,9466             |
| <b>Sub total = C<sub>WT-TF</sub></b> |                  |                               |                     |                                | 934,617             |

**Step 03:** - Cost for Cabling from transformer to BFPs

$$\text{Cabling cost from transformer to motor of BFP} = 800 \text{ US\$/m} \times 500 \text{ m}$$

$$(3 \text{ Core, Armed } 400 \text{ mm}^2 \text{ cable}) = \text{US\$ } 0.4 \text{ M}$$

$$\therefore \text{Cabling cost for 2 Motors} = \text{US\$ } 0.4 \text{ M} \times 2 = \text{US\$ } 0.8 \text{ M}$$

**Step 04:** - Calculation for total implementation cost for wind sources

$$\text{Total cost to implimet wind energy} = C_{WT} + C_{WT-TF} + C_{TF} + C_{TF-Motor}$$

$$\begin{aligned} \therefore \text{Total impl. cost} - \text{wind energy} &= \text{US}\$(25 \text{ M} + 0.93 \text{ M} + 0.95 \text{ M} + 0.8 \text{ M}) \\ &= \text{US}\$ 27.68 \text{ M} \end{aligned}$$

$$\begin{aligned} \therefore \text{Cost involvement from transformer to motor} &= C_{TF} + C_{TF-Motor} \\ &= \text{US}\$(0.95 \text{ M} + 0.8 \text{ M}) = \text{US}\$ 1.75 \text{ M} \end{aligned}$$

- According to the report of wave power conversion systems for electrical energy production, installation cost of wave energy extractor is 600,000 €/MW [47].

$$\therefore \text{Cost for extractor} = 600,000 \text{ €/MW} \times 11 \text{ MW} = \text{€ } 6.6 \text{ M}$$

- According to the rates of currency exchange on 07<sup>th</sup> May 2015,

$$\therefore \text{Cost for extractor in USS\$} = 9.32 \text{ M}$$

$$\begin{aligned} \text{Total cost to implimet wave energy} &= C_{\text{Extractor.}} + [C_{TF} + C_{TF-Motor}] \\ &= \text{US}\$(9.32 \text{ M} + 1.75 \text{ M}) \\ &= \text{US}\$ 11.07 \text{ M} \end{aligned}$$

➤ Implementation cost for solar energy sources

- According to the report of The Economics of Solar Electricity which was prepared by Erin Baker, Meredith Fowlie, Derek Lemoine, and Stanley Reynolds, installation costs for solar power generation related to the different sites are noted in Table 4.22 [67].

Table 4.4.22 : Installation cost of few solar projects in USA

| Location          | Panel Orientation | Installed cost (US\$/W) |
|-------------------|-------------------|-------------------------|
| Boston, MA        | South- West       | 6.1                     |
| Trenton, NJ       | South- West       | 5.9                     |
| Tucson, AZ        | South- West       | 5.2                     |
| San Francisco, CA | South- West       | 6.4                     |

- If the average installed cost of the above sites are taken as the installation cost of solar collector and its auxiliaries, cost for transformer and the cost for the power cabling from transformer to BFP motor are the same as the cost for wind energy and sea wave energy.

 University of Moratuwa, Sri Lanka.  
 Electronic Theses & Dissertations  
 www.lib.mrt.ac.lk

$$\begin{aligned}
 \text{Average installed cost for PV collectors} &= \frac{(6.1 + 5.9 + 5.2 + 6.4)}{4} \text{ US\$/W} \\
 &= 5.9 \text{ US\$/W}
 \end{aligned}$$

$$\begin{aligned}
 \therefore \text{Cost for solar collector installation} &= C_{\text{Solar Colle.}} = 5.9 \text{ US\$/W} \times 11.28 \times 10^6 \\
 &= \text{US\$ } 66.55 \text{ M}
 \end{aligned}$$

$$\begin{aligned}
 \text{Cost involvement from transformer to motor} &= C_{TF} + C_{TF-Motor} \\
 &= \text{US\$}(0.95 \text{ M} + 0.8 \text{ M}) = \text{US\$ } 1.75 \text{ M}
 \end{aligned}$$

$$\begin{aligned}
 \therefore \text{Total cost to impliment solar energy} &= C_{\text{Solar Colle.}} + [C_{TF} + C_{TF-Motor}] \\
 &= \text{US\$}(66.55 \text{ M} + 1.75 \text{ M}) \\
 &= \text{US\$ } 68.3 \text{ M}
 \end{aligned}$$

Table 4.4.23 : Summary of implementation cost in NCPP

| Energy source                                 | Implementation cost (US\$) |
|---|----------------------------|
| Mechanical Power sources                      | N/A                        |
| Super-heated steam sources with steam turbine | 4.83 M                     |
| Wind power source + Generator                 | 27.68 M                    |
| Sea waves + Generator                         | 11.07 M                    |
| Solar power                                   | 68.30 M                    |

#### 4.5 Analysing the alternative sources in applicable to the NCPP

There are several alternative power sources, such as mechanical power, superheated steam sources, wind power, sea wave energy and solar power sources related to the site of Norochcholai coal power plant which have been identified. When analysing the solutions, it needs to check the feasibility of each alternative source. For this, the previously studied feasibility factors are used. It is more expedient to compare each of the power sources with reference to the discussed feasibility factors in quantitative or qualitative manner.

Table 4.4.24 : Comparison of feasibility factors of alternative power sources

| <b>Power source</b> | <b>Factor Availability</b> | <b>Requirement of design changes</b> | <b>Satisfaction of BFP's demand</b> | <b>Cost (US\$)</b> |
|---------------------|----------------------------|--------------------------------------|-------------------------------------|--------------------|
| Mechanical          | Excellent                  | Total design change                  | ---                                 | ---                |
| Steam Ex#1          | Excellent                  | Moderate changes                     | Satisfied                           | 4.83 M             |
| Steam Ex#2          | Excellent                  | Moderate changes                     | Not enough                          | 4.83 M             |
| Steam Ex#3          | Excellent                  | Moderate changes                     | Satisfied                           | 4.83 M             |
| Steam Ex#4          | Excellent                  | Moderate changes                     | Not enough                          | 4.83 M             |
| Wind                | Good                       | Minor change                         | Not enough                          | 27.68 M            |
| Sea wave            | Average                    | Minor change                         | Satisfied                           | 11.07 M            |
| Solar               | Average                    | Minor change                         | Satisfied                           | 68.30 M            |

#### 4.6 Selecting the suitable solution for NCPP

The key solution for Norochcholai power plant is selected based on summarised feasibility factors which are mentioned in Table 4.24. When considering the mechanical power sources, power transmission is very difficult although its availability is much higher. Furthermore it needs total design change of the power plant. In the case of utilisation of steam source as an alternative solution, its availability is almost 100% and easiness of power transmission is not difficult as mechanical sources. Even though the potential of some steam extractions are not enough to fulfil the demand of BFPs, extraction #1 and #3 fulfil the demand. Design modification on the power plant in relation to the utilisation of steam sources is not required for total design changes. It needs moderate changes. The most important

thing is the requirement of low implementation cost. When considering the wind energy sources, its level of power transmission easiness and requirements for design changes are favourable although it does not fulfilled the demand of BFPs and also the availability of it is not very high. The implementation coast is also a little higher than the cost for utilisation of steam sources or sea wave sources.

Good favourable levels for some feasibility factors such as the easiness of power transmission, requirement of design changes and ability to fulfil the demand of BFPs related to the sea wave power can be seen. Its availability is not at high level, because the BFPs in coal power plant are continuously operated. Therefore the availability of the source is very important. When considering the solar power, its availability is very low although some feasibility factors such as the easiness of power transmission, requirement of design changes and ability to fulfil the demand of BFPs are favourable. The implementation cost for solar power source is comparatively high.

By considering all of the above facts, extraction of steam source #1 and #3 are the most suitable solutions to substitute the electrically operated boiler feed system in the site of Norochcholai power plant.

University of Moratuwa, Sri Lanka  
Electronic Theses & Dissertations  
www.lib.mrt.ac.lk

#### **4.7 Evaluation and justification of the study**

Although the steam sources have been selected as the most suitable solution, it is necessary to justify its outcomes and benefits separately for steam extraction #1 and steam extraction #3. To justify the outcomes, it needs a mathematical evaluation in accordance with the Norochcholai power plant.

##### **4.7.1 Argument of the evaluation**

- When operating the plant at 300 MW (at plant rated power), 271.8 MW power is supplied to the national grid. 10.78 MW power out of 28.2 MW home load is consumed by motors of boiler feed pumps.
- Therefore 17.42 MW of 28.2MW is consumed by all other auxiliary equipments and 17.42 MW power can be considered as constant at plant rated condition.

- If the grid power requirement does not vary for a certain time period, 271.8 MW power should be supplied by the power plant.
- If the 10.78 MW required power for BFP does not taken from plant generated power and grid power requirement is not vary, simultaneously plant should be de-loaded by 10.78 MW. The boiler operation in out of plant rated condition is a disadvantage financially.
- Therefore during the boiler operation in rated power conditions (at 300 MW), there is some possibility to extract excessive steam through extractions of the turbine, because of the electricity generation by generator is done with lack of 10.78 MW power. Although the generator power output is changed in to 289.22 MW in this scenario, grid connected 271.8 MW power or 17.42 MW power of other auxiliary equipment is not changed
- On this condition, four steam extraction sources have been identified. Source at extraction #1 and extraction #3 satisfy the power requirement of introduced steam turbine of the BFP. This can be clearly identified from Table 4.25.

Table 4.25 : Summary of extra steam capacities at 289.22 MW

| Steam Source                     | Available steam capacity (kg/s) | Required steam capacity for BFP (kg/s) | Extra steam capacity (kg/s) |
|----------------------------------|---------------------------------|--|-----------------------------|
| Extraction #1<br>(Inlet of HPT)  | 11.43                           | 10.5                                   | 0.93                        |
| Extraction #3<br>(Hot Re-heater) | 12.74                           | 9.6                                    | 3.14                        |

When boiler operates at 300 MW, the generator produces 289.22 MW Power with extractable steam flow of 11.43 kg/s at extraction #1 or steam flow of 12.74 kg/s at extraction #3. These steam flows not only fulfil, but also exceeds the requirement of relevant steam turbine. Extra steam capacities of 0.93 kg/s and 3.14 kg/s are respectively available during these extractions. This extra steam amount can be directly dropped into the condenser. Since the dropping of live steam into condenser

is an energy waste, there are two ways which can be applied to take exactly 10.5 kg/s or 9.6 kg/s steam flows through the selected extractions [16].

- i. De-loading the boiler with respect to the extra steam capacity of 0.93 kg/s or 3.14 kg/s from boiler rated capacity to little lower capacity.
- ii. Increasing the generator output from 289.22 MW to little higher power

As discussed earlier, operation of the boiler in an out rated condition courses considerable economic disadvantages. Therefore increasing the load a little is the only possible way. But there are some limitations to this because it may not be a considerable load increase with respect to the extra steam capacities. Sometimes the power may be negligible. Therefore a further assessment of these results is required although the feed pumps are fully energised by steam sources available at the site. If there is no further gain between the two methodologies of boiler feed pumps energisation, changing the existing mechanism may be a useless attempt.

#### 4.7.2 Evaluation of the outcomes - reference to the steam extraction #1

It is considered that there is no further extra steam availability at extraction #1. Available steam capacity of 10.5 kg/s exactly fulfils the requirement of steam turbine of BFPs. Therefore the amount of 0.93 kg/s steam flow is involved with further power increase to more than 289.22 MW. If  $x$  MW is considered as the new power output of the main generator, power gain through the main turbine can be calculated with reference to the extra steam quantity of 0.9 kg/s.

$$\begin{aligned} \dot{m}_{HP@300MW} - \dot{m}_{HP@xMW} &= 10.5 \text{ kg/s} \\ 211.78 \text{ kg/s} - \dot{m}_{HP@xMW} &= 10.5 \text{ kg/s} \\ \therefore \dot{m}_{HP@xMW} &= 201.28 \text{ kg/s} \end{aligned}$$

That means, 201.28 kg/s rate of steam flow is expanded through the HP rotor.

$$\begin{array}{l} \text{Power through} \\ \text{HP turbine} \end{array} = \begin{array}{l} \text{Steam flow rate} \\ \text{through HP turbine} \end{array} \times \begin{array}{l} \text{Enthalpy difference} \\ \text{through HP turbine} \end{array}$$

Except the steam flow rate of turbine inlets, other parameters are not changed in the boiler. Because of the boiler is operated continuously at rated condition.

∴ Boiler operation conditions; [16]

$$\text{Main steam pressure} = 16.7 \text{ MPa}$$

$$\text{Main steam temperature} = 538 \text{ }^\circ\text{C}$$

According to the Figure 4.4, inlet and outlet of the HP turbine are represented by point 1 and point 2 respectively.

$$\therefore h_{1@xMW} = 3396.9 \text{ kJ/kg} \quad \& \quad h_{2@xMW} = 3048.9 \text{ kJ/kg}$$

$$P_{HP@xMW} = 213.66 \text{ kg/s} \times (3396.9 - 3048.9) \text{ kJ/kg}$$

$$P_{HP@xMW} = 70786.25 \text{ kW} = 70.78 \text{ MW}$$

Due to 95.25% efficiency of HP rotor; [16]

$$\text{Output power of the HP turbine} = \frac{\text{Operating power of HP turbine}}{\text{Efficiency of HP rotor}}$$

$$P_{HP@xMW(out)} = P_{HP@xMW} \times \eta_{HP}$$

$$P_{HP@xMW(out)} = 70.78 \text{ MW} \times 0.9525$$

$$P_{HP@xMW(out)} = 70.29 \text{ MW}$$

Power ratio of combined rotor shaft; [16]

$$P_{HP} : P_{IP} : P_{LP1} : P_{LP2} = 0.2410 : 0.2712 : 0.2439 : 0.2439$$

∴ Turbine power ratios when generator producing  $x$  MW power,

$$P_{HP@xMW(out)} : P_{IP@xMW(out)} : P_{LP@xMW(out)} = 0.2410 : 0.2712 : 2 \times 0.2439$$

$$70.29 \text{ MW} : P_{IP@xMW(out)} : P_{LP@xMW(out)} = 0.2410 : 0.2712 : 0.4878$$

$$\frac{70.29 \text{ MW}}{P_{IP@xMW(out)}} = \frac{0.2410}{0.2712} \quad \& \quad \frac{70.29 \text{ MW}}{P_{LP@xMW(out)}} = \frac{0.2410}{0.4878}$$

$$\therefore P_{IP@xMW(out)} = 79.1 \text{ MW}$$

$$\therefore P_{LP@xMW(out)} = 142.27 \text{ MW}$$

Overall power output of the turbine is a combination of individual power output of the HP, IP and LP rotors.

$$\text{Turbine overall power output} = P_{HP@xMW(out)} + P_{IP@xMW(out)} + P_{LP@xMW(out)}$$

$$P_{\text{Overall output @xMW}} = 70.29 \text{ MW} + 79.1 \text{ MW} + 142.27 \text{ MW}$$

$$P_{\text{Overall output @xMW}} = 291.66 \text{ MW}$$

Generator is directly coupled to the main turbine shaft.

$$\therefore P_{\text{Overall output @xMW}} = P_{\text{input to Gen}}$$

$$P_{\text{input to Gen}} = 291.66 \text{ MW}$$

Due to 99.25% efficiency of the generator, [16]

$$\frac{\text{Output power of the Generator}}{\text{of the Generator}} = \frac{\text{Input power of Generator}}{\text{of Generator}} \times \frac{\text{Efficiency of Generator}}{\text{Generator}}$$

$$P_{xMW} = P_{\text{input to Gen}} \times \eta_{\text{Generator}}$$

$$P_{yMW} = 291.66 \text{ MW} \times 0.9925 = 289.47 \text{ MW}$$

### 4.7.3 Evaluation of the outcomes - reference to the steam extraction #3

It is considered that there is no further extra steam availability at extraction #3. The available steam capacity of 9.6 kg/s exactly fulfils the requirement of steam turbine of BFPs. Therefore the amount of 3.4 kg/s steam flow is involved with further power increase to more than 289.22 MW. If  $y$  MW is considered as the new power output

of the main generator, power gain through the main turbine can be calculated with reference to the extra steam quantity of 3.4 kg/s.

$$\dot{m}_{IP@300MW} - \dot{m}_{IP@yMW} = 9.6 \text{ kg/s}$$

$$223.26 \text{ kg/s} - \dot{m}_{IP@yMW} = 9.6 \text{ kg/s}$$

$$\therefore \dot{m}_{IP@yMW} = 213.66 \text{ kg/s}$$

That means, 213.66kg/s rate of steam flow is expanded through the IP rotor.

$$\begin{aligned} \text{Power through} \\ \text{IP turbine} \end{aligned} = \begin{aligned} \text{Steam flow rate} \\ \text{through IP turbine} \end{aligned} \times \begin{aligned} \text{Enthalpy difference} \\ \text{through IP turbine} \end{aligned}$$

$$P_{IP@yMW} = \dot{m}_{IP@yMW} \times (h_{3@yMW} - h_{4@yMW})$$

Except the steam flow rate of turbine inlets, other parameters are not changed in the boiler, because the boiler is operated continuously at rated condition.

 [www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)  
 Electronic Theses & Dissertations  
 University of Moratuwa, Sri Lanka

$\therefore$  Boiler operation conditions; [16]

$$\text{Main steam pressure} = 16.7 \text{ MPa}$$

$$\text{Main steam temperature} = 538 \text{ }^\circ\text{C}$$

According to the Figure 4.4, inlet and outlet of the IP turbine are represented by point 3 and point 4 respectively.

$$\therefore h_{3@yMW} = 3535.9 \text{ kJ/kg} \quad \& \quad h_{4@yMW} = 3168.7 \text{ kJ/kg}$$

$$P_{IP@yMW} = 213.66 \text{ kg/s} \times (3535.9 - 3168.7) \text{ kJ/kg}$$

$$P_{IP@yMW} = 79886.32 \text{ kW} = 79.89 \text{ MW}$$

Due to 96.9% efficiency of IP rotor; [16]

$$\begin{aligned} \text{Output power} \\ \text{of the IP turbin} \end{aligned} = \begin{aligned} \text{Operating power} \\ \text{through IP turbine} \end{aligned} \times \begin{aligned} \text{Efficiency of} \\ \text{IP rotore} \end{aligned}$$

$$P_{IP@yMW(out)} = P_{IP@yMW} \times \eta_{IP}$$

$$P_{IP@yMW(out)} = 79.89 \text{ MW} \times 0.969$$

$$P_{IP@yMW(out)} = 79.24 \text{ MW}$$

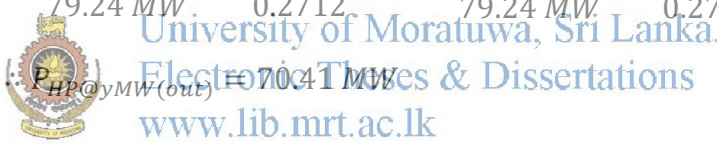

Power ratio of combined rotor shaft; [16]

$$P_{HP} : P_{IP} : P_{LP1} : P_{LP2} = 0.2410 : 0.2712 : 0.2439 : 0.2439$$

∴ Turbine power ratios when generator producing y MW power,

$$P_{HP@yMW(out)} : P_{IP@yMW(out)} : P_{LP@yMW(out)} = 0.2410 : 0.2712 : 2 \times 0.2439$$

$$P_{HP@yMW(out)} : 79.24 \text{ MW} : P_{LP@yMW(out)} = 0.2410 : 0.2712 : 0.4878$$

$$\frac{P_{HP@yMW(out)}}{79.24 \text{ MW}} = \frac{0.2410}{0.2712} \quad \& \quad \frac{P_{LP@yMW(out)}}{79.24 \text{ MW}} = \frac{0.4878}{0.2712}$$

$$\therefore P_{LP@yMW(out)} = 142.53 \text{ MW}$$

Overall power output of the turbine is a combination of individual power output of the HP, IP and LP rotors.

$$\text{Turbine overall power output} = P_{HP@yMW(out)} + P_{IP@yMW(out)} + P_{LP@yMW(out)}$$

$$P_{\text{Overall output @yMW}} = 70.41 \text{ MW} + 79.24 \text{ MW} + 142.53 \text{ MW}$$

$$P_{\text{Overall output @yMW}} = 292.18 \text{ MW}$$

Generator is directly coupled to the main turbine shaft.

$$\therefore P_{\text{Overall output @yMW}} = P_{\text{input to Gen}}$$

$$P_{\text{input to Gen}} = 292.18 \text{ MW}$$

Due to 99.25% efficiency of the generator; [16]

$$\frac{\text{Output power of the Generator}}{\text{Input power of Generator}} = \text{Efficiency of Generator}$$

$$P_{yMW} = P_{input\ to\ Gen} \times \eta_{Generator}$$

$$P_{yMW} = 292.18\ MW \times 0.9925 = 289.98\ MW$$

#### 4.7.4 Justification of the solutions

As per the calculations which were done for the two instances, there are some power gains when operating the plant at its rated conditions. In the other round, the boiler usually generates the same capacity under the same conditions. Therefore the required fuel rate or coal supplying rate does not change. In addition, extra energy or money is not required. This scenario is the same to the case when operating power plant is operated with electrically driven feed pumps. Because, the power capacity of grid supplying is 271.8 MW and home load requirement of 17.42 MW for other auxiliary equipment do not change. The only thing that changes is the generator produced power without 10.78 MW capacity which was previously used for the motor of BFPs. Instead, a steam capacity of 10.5 kg/s through extraction #1 or a steam capacity of 9.6 k g/s through extraction #3 is used for steam turbines attached BFPs. According to the above calculation, some quantity of power gain is available beyond the expected generation of 289.22 MW in each case. This improvement can be easily understood by referring to Tables 4.26 and 4.27.

Table 4.4.26 : Grid supplied power after implementing new solution

|        | Used Steam Source                | Generator power output (MW) | Home load(MW) | Grid Supplied power (MW) |
|--------|----------------------------------|-----------------------------|---------------|--------------------------|
| Case-1 | Extraction #1<br>(Inlet of HPT)  | 289.47                      | 17.42         | 272.05                   |
| Case-2 | Extraction #3<br>(Hot Re-heater) | 289.98                      | 17.42         | 272.56                   |

Table 4.4.27 : Power gain after implementing new solution

|        | Grid Supplied power (MW)                      |                             | Power gain (MW) |
|--------|---|-----------------------------|-----------------|
|        | With implementation of steam turbine for BFPs | With existing motor of BFPs |                 |
| Case-1 | 272.05  | 271.8                       | 0.25            |
| Case-2 | 272.56  | 271.8                       | 0.76            |

It can be clearly observed that, some quantity of power gain in each of cases. Therefore it needs some technical and economical evaluation such as power saving, financial saving and payback period on each of case to discuss the feasibility of implementations. Sometimes, considerable financial gain cannot be achieved even though some power saving is obtained. It may take a long time to payback and to recover the cost of implementation. Therefore it is essential to discuss these technical and economic terms.

- Calculation of annual power saving for case #1

$$\text{Annual power saving} = \text{Power gain} \times 24 \times 365 \times \text{Plant factor}$$

According to the design specifications of 300 MW Norochcholai coal power plant, expected plant factor is 88% [16].

$$\therefore \text{Annual power saving} = 0.25 \times 10^3 \times 24 \times 365 \times 0.88 \text{ kWhr}$$

$$\therefore \text{Annual power saving} = 1,927,200.00 \text{ kWhrs} = 1,927.2 \text{ MWhrs}$$

- Calculation of annual power saving for case #3

$$\text{Annual power saving} = \text{Power gain} \times 24 \times 365 \times \text{Plant factor}$$

According to the design specifications of 300 MW Norochcholai coal power plant, expected plant factor is 88% [16].

$$\therefore \text{Annual power saving} = 0.76 \times 10^3 \times 24 \times 365 \times 0.88 \text{ kWhr}$$

$$\therefore \text{Annual power saving} = 5,858,688.00 \text{ kWhrs} = 5,858.7 \text{ MWhrs}$$

- Calculation of annual financial saving for case #1

$$\therefore \text{Annual Finan. saving} = \text{Annual power saving} \times \text{Unit gene. cost}$$

According to the 2013 annual report of energy purchasing and distribution by Ceylon Electricity Board, unit generation cost at 300 MW Norochcholai coal power plant is 8.00 LKR/kWhrs [18].

$$\therefore \text{Annual Financial saving} = 1,927,200.00 \text{ kWhrs} \times 8.00 \text{ LKR/kWhr}$$

$$\therefore \text{Annual Financial saving} = 15,417,600.00 \text{ LKR/year}$$

- Calculation of annual financial saving for case #3

$$\therefore \text{Annual Financial saving} = \text{Annual power saving} \times \text{Unit generation cost}$$

According to the 2013 annual report of energy purchasing and distribution by Ceylon Electricity Board, unit generation cost at 300 MW Norochcholai coal power plant is 8.00 LKR/kWhrs [18].

$$\therefore \text{Annual Financial saving} = 5,858,688.00 \text{ hrs} \times 8.00 \text{ LKR/kWhr}$$

$$\therefore \text{Annual Financial saving} = 46,869,504.00 \text{ LKR/year}$$

US\$ 4.83 M is required to introduce a steam turbine driven boiler feeding system for the existing coal power plant which is being operated with electric motor. According to the currency exchange rates on 07<sup>th</sup> May 2015, it is nearly 603,750,000.00 LKR.

- Calculation of payback time for case #1

$$\text{Payback period} = \frac{\text{Implementation cost}}{\text{Annual Financial saving}}$$

$$\therefore \text{Payback period} = \frac{603,750,000.00 \text{ LKR}}{15,417,600.00 \text{ LKR/year}}$$

$$\text{Payback period} = 39.16 \text{ years} \approx 39 \text{ years}$$

- Calculation of payback time for case #3

$$\therefore \text{Payback period} = \frac{603,750,000.00 \text{ LKR}}{46,869,504.00 \text{ LKR/year}}$$

$$\text{Payback period} = 12.88 \text{ years} \approx 12 \text{ years}$$

- Calculation of coal saving for case #1

$$\begin{aligned}
 \text{Coal requirement for generating 300 MW [16]} &= 100 \text{ T/hrs} \\
 \text{Required coal quantity for 1 MWhrs} &= 0.33 \text{ T/MWhrs} \\
 \text{Annual power saving} &= 1,927.2 \text{ MWhrs} \\
 \text{Annual coal saving} &= \text{Annual power saving} \times 0.33 \text{ T/MWhrs} \\
 \text{Annual coal sa} &= 1,927.2 \text{ MWhrs} \times 0.33 \text{ T/MWhrs} \\
 \text{Annual coal saving} &= 636.3 \text{ T/year}
 \end{aligned}$$

- Calculation of coal saving for case #3

$$\begin{aligned}
 \text{Coal requirement for generating 300 MW [16]} &= 100 \text{ T/hrs} \\
 \text{Required coal quantity for 1MWhrs} &= 0.33 \text{ T/MWhrs} \\
 \text{Annual power saving} &= 5,858.7 \text{ MWhrs} \\
 \text{Annual coal saving} &= \text{Annual power saving} \times 0.33 \text{ T/MWhrs} \\
 \text{Annual coal saving} &= 5,858.7 \text{ MWhrs} \times 0.33 \text{ T/MWhrs} \\
 \text{Annual coal saving} &= 1,952.9 \text{ T/year}
 \end{aligned}$$

39 years and 12 years payback times are respectively required for recovering the investment on implementation of each case. In addition, to fulfil the technical feasibility of a solution, it is an imperative need to get a decision based on economic factors such as payback time and return of investment. The overall lifetime of coal power plant is 30 years [18]. Therefore solution in case #1 can be avoided although all other technical factors are satisfactory. The solution which was discussed in case #3 is the only solution which fulfils both technical and economic factors.

#### 4.8 Outcomes of the implementation

When using #3 extraction steam as alternative energy option in Norochcholai power plant, grid supply is gained by 0.76 MW power capacity with the same unit operation in rated condition. This gain proves that the home load is minimised by 0.76 MW.

Table 4.4.28 : Outcomes of the study with related to #3 extracted steam

| <b>Factor</b>           | <b>Outcome</b> |
|-------------------------|----------------|
| Grid supply power gain  | 0.76 MW        |
| Annual power saving     | 5,858.7 MWhrs  |
| Annual financial saving | LKR 46.9 M     |
| Payback period          | 12 years       |
| Annual coal saving      | 1,952.9 T      |

## CHAPTER 5 - CASE GENERALISATION

During the case study in Norochcholai Coal Power Plant, all outcomes were calculated based on plant's rated load condition. This kind of coal power plant can operate beyond its rated load conditions. At those times, these outcomes may be changed according to its operated load conditions. To make the outcomes more general, it requires calculating relevant achievements with some range of load conditions beyond the rated load of a power plant.

As the first step of case generalisation, history of generated power output of one unit of Norochcholai Coal Power Plant was extracted for a certain period through DCS. Generated power out of unit 2 from September 1st, 2014 to December 28th, 2015 was weekly averaged and plotted. See Figure 5.1

According to the load variation which is shown in the graph on Figure 5.1, it can be observed some specific load conditions which were plant operated. These load conditions are 300 MW (Plant rated condition), 285 MW, 270 MW, 240 MW, 200MW, 180 MW, 150 MW (Half load condition), 140 MW and 130MW. The main outcomes which describe in section 4.8, were calculated for each load conditions. For easiness of calculations, a dedicated programme was created by using EES based on the equations and conditions which are met on developed method in chapter 3. EES code of the programme is attached in appendix D.

The main outcomes with reference to the each load conditions which are extracted through developed EES programme is summarised in Table 5.1. In addition to the results which were obtained in above mentioned specific load conditions in Table 5.1, there can be operated a coal power plant in different power condition in its operation time. To obtain the results in each load condition, main five outcomes were separately plotted against operation conditions of the power plant.

Variation of grid supplied power gain, variation of annual power saving, variation of annual financial saving, variation of payback period and variation of annual coal saving with reference to the operation condition of the power plant are respectively shown in Figure 5.2, Figure 5.3, Figure 5.4, Figure 5.5 and Figure 5.6 as graphs.

## CHAPTER 6 - DISCUSSION

### 6.1 Positive approach of the method

Alternative energy options and their nature in a particular coal power plant can be identified through this method. During this identification, the availability of alternative power sources and power potential of the sources are notified. This is very important for the organisation using coal power plant, because they can update their knowledge regarding the power capacities or alternatives around the power plant. Then they can try for similar additional implementations based on the available alternative power sources.

By using this method, the most suitable and feasible solution or solutions in relation to the coal power plants can be easily identified. The problem of minimising the home load and finding a feasible solution for coal power plant will not arise if this method is used. If this method is applied to a coal power plant and if its site available alternative energy options are feasible, the home load can be decreased. The grid supplied power can be increased. As a result, energy and money can be saved. Also saving a small power capacity in such a mega range power plant will lead to a massive saving for the power plant. After calculating the payback period with reference to the life time of the considered power plant, the feasibility of the solutions can be confirmed. From the payback period it is possible to evaluate the results off this method.

When the feasible alternative energy options selected through this method is implemented, a considerable annual saving of coal can be expected. Coal is one type of fossil fuel. It is a non-renewable resource. Although these non-renewable sources are used for the present power generation as our wish, they have been borrowed from future generation. As human beings, it is responsibility to save these no-renewable sources for future generation. After implementing this method, there will be a considerable saving of coal annually and a huge coal saving can be expected over the remaining life time of the power plant. This is the most important and valuable outcome of this method.

With reference to the Norochcholai coal power plant, the solution from the case study substitutes a steam turbine with extracted steam from extraction #1 or extraction #3 instead of the motor of boiler feed pumps. Among these extractions, operating a steam turbines with extracted steam from extraction #3 is the only suitable solution, because the payback time is nearly 12 years. The life time of the Norochcholai power plant is 30 years and it has been in operation for 4 years now. If this solution is implemented for the Norochcholai power plant today, nearly 14 years will remain to obtain benefits after the payback period. This means that nearly amount of 656.17M LKR will be saved or 82.02 GWhrs can be additionally generated. Further 27,340 Tons of coal will be saved for the future during these 14 years.

## 6.2 Generalisation of the method

Although this method is evaluated as a case study applicable to the Norochcholai coal power plant, this method can be commonly used for other existing coal power plants which have been constructed and are being operated with electric boiler feed pumps. By applying this method for a few selected coal power plants with different designs and in different geographical localisation, generalisation of the method can be proved. The concept of the method is common for all power plants.

## 6.3 Limitations

Using this method to a specific coal power plant as well as all power plants, some limitations can be observed. The most popular alternative energy options which were listed in previous research articles and also identified in the literature review only focused on the method. Although it is agreed that it is suitable for most of the coal power plants, there is a possibility to identify some coal power plants with different alternative energy options. For example, Tanjung Jati-B coal fired power plant is located in Central Java province, Indonesia (Location- 6°26'43"S 110°44'37"E) [89]. 180 MW Mount Salak geo thermal power station (Location 6°27'S 109°54'E) is being operated with closer to Tanjung Jati-B power plant[90]. It has been identified that additional geo thermal power potential of 210 MW is available in the valley of Mount Salak [90]. Therefore in the case of Tanjung Jati-B power plant, geo thermal

sources can be more dominant than the most popular energy options which were listed in the literature review.

When selecting a renewable energy source as the most suitable solution among all alternative energy sources, feasibility of the solution can be changed a little with the way of data collected.

Maximum outcomes can be achieved only for the power plants which were constructed and had been operated for a short time over its plant life time. When considering a power plant with one or two years remaining life, technical and economic outcomes may not be worth.

In this study, it is tried to provide solutions only for motor of boiler feed pump as key contributor to the plant home load. Sometimes, there may be other pumps with considerable power consumption although they are not much influenced as boiler feed pumps. Due to concentrating only on the feed pumps, outcomes can be limited in this method.

## CONCLUSIONS AND RECOMMENDATIONS

Under the present situation of energy crisis, energy saving and minimising losses are very popular topics. Among the ways which are used to minimise losses, optimisation of the existing systems and introducing alternative solutions are dominant. There are some considerable losses are being occurred in a coal power plant related to the home load. Many auxiliary equipment such as pumps, fans, cranes, and compressors are contributed to the plant home load. The boiler feed water system consumes a large portion of the home load. Therefore prime movers of feed pumps contribute automatically for a large percentage of the losses which occur in the power plant.

Motors of feed pumps are key players in the problem in such power plants. Therefore doing optimisations or introducing feasible alternative energy options related to the boiler feed system, more energy gain and financial benefits can be expected. Based on the above logic and the method which has been developed in chapter three and developed graphs related to the main outcomes in chapter five, energy and financial benefits can be generally obtained and estimated in coal power plants.

If the range of the most popular alternative energy options applicable to the coal power plants is expanded, the developed method will be more generalised. Energy gain and financial benefit can be increased by considering other major contributors of plant home load in addition to its key player. When selecting a renewable energy source as the most suitable solution among all the alternative energy sources, accurate data collection procedures and calculation method can be used to increase the reliability of the solution. To make it easy for the users, a dedicated computer programme can be developed based on the framework of the method with all possible inputs. Then results or outcomes can be extracted in a convenient manner.

# APPENDIX A: SITE LAYOUT OF NOROCHCHOLAI COAL POWER PLANT

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
[www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

## APPENDIX B: EQUIPMENT LAYOUT DRAWING OF MPB IN NCPP

# APPENDIX C: EQUIPMENT ARRANGEMENT DRAWING OF MPB IN NPP

University of Moratuwa, Sri Lanka.  
Electronic Theses & Dissertations  
[www.lib.mrt.ac.lk](http://www.lib.mrt.ac.lk)

## APPENDIX D: EES CODE OF THE PROGRAMME TO CALCULATE OUTCOMES

EES program to find steam mass flow rate

H\_1=Enthalpy(steam, P=P\_1, T=T\_1)

H\_2=Enthalpy(steam, T=T\_2,X=X\_2)

S\_1=Entropy(steam, P=P\_1, T=T\_1)

S\_2=Entropy(steam, T=T\_2,X=X\_2)

P\_2=Pressure(steam, T=T\_2,X=X\_2)

P\_pump=5400[kW]

eta=0.75

m=P\_pump/(H\_1-H\_2)/eta

"As a percentage of BMCR"

Per\_BMCR=2\*m\*3600[s/h]/1000[kg/t]/1025[t/h]\*100

EES program to analyze the current thermodynamic cycle of the power plant without an extraction for the BFPT (i.e. with a motor driven BFP)

"-----"

P : Pressure in MPa

T: Temperature in C

G: Steam mass flow in kg/h

H: Enthalpy in kJ/kg

-----"

P\_1=16700[kPa]

T\_1=538[C]

G\_1=964000[kg/h]

H\_1=Enthalpy(steam, P=P\_1, T=T\_1) {3396.9[kJ/kg]}

S\_1=Entropy(steam, P=P\_1, T=T\_1)

P\_2=3913[kPa]

T\_2=331.2[C]  
G\_2=799380[kg/h]  
H\_2=Enthalpy(steam, P=P\_2, T=T\_2) {3049.4[kJ/kg]}  
S\_2=Entropy(steam, P=P\_2, T=T\_2)

P\_3=3521[kPa]  
T\_3=538[C]  
G\_3=799380[kg/h]  
H\_3=Enthalpy(steam, P=P\_3, T=T\_3) {3536.0[kJ/kg]}  
S\_3=Entropy(steam, P=P\_3, T=T\_3)

P\_4=951[kPa]  
T\_4=355.5[C]  
G\_4=726850[kg/h]  
H\_4=Enthalpy(steam, P=P\_4, T=T\_4) {3170.1[kJ/kg]}  
S\_4=Entropy(steam, P=P\_4, T=T\_4)

P\_5=9.7[kPa]  
T\_5=45.2[C]  
G\_5=610560[kg/h]  
H\_5=2404.2[kJ/kg]  
X\_5=Quality(steam, H=H\_5, T=T\_5)  
S\_5=Entropy(steam, P=P\_5, X=X\_5)

P\_6=Pressure(steam, T=T\_6, H=H\_6)  
T\_6=45.2[C]  
G\_6=G\_7  
H\_6=189.3[kJ/kg]  
S\_6=Entropy(steam, H=H\_6, T=T\_6)

$$P_{Gen}=(P_{hpt}+P_{ipt}+P_{lpt})*\eta_{mech\_turb}*\eta_{elec\_gen}$$

$$HR_{gross\_motor}=(G_1*(h_1-h_{16})+G_3*(h_3-h_2))/3600[s/h]`/1000[kW/MW]/P_{Gen}$$

$$HR_{net\_motor}=(G_1*(h_1-h_{16})+G_3*(h_3-h_2))/3600[s/h]`/1000[kW/MW]/(P_{Gen}-P_{bfpm})$$

EES program to find steam extraction point for BFPT

Four different EES programs were created for each extraction point and only the program for extraction point A is shown here.

"-----

P : Pressure in MPa

T: Temperature in C

G: Steam mass flow in kg/h

H: Enthalpy in kJ/kg

-----"

P\_1=16700[kPa]

T\_1=538[C]

G\_1=G\_1\_0-G\_1\_1

H\_1=Enthalpy(steam, P=P\_1, T=T\_1) {3396.9[kJ/kg]}

S\_1=Entropy(steam, P=P\_1, T=T\_1)

{SH outlet of boiler }

P\_1\_0=16700[kPa]
