Thesis submitted in partial fulfillment of the requirements for the degree Master
of Science in Electrical Engineering

Department of Electrical Engineering

University of Moratuwa

Sri Lanka

August 2019

DECLARATION

I declare that this is my own work and this dissertation does not incorporate without acknowledgment any material previously submitted for a Degree or Diploma in any other University or institute of higher learning and to the best of my knowledge and belief it does not contain any material previously published or written by another person except where the acknowledgment is made in the text.

Also, I hereby grant to University of Moratuwa the non-exclusive right to reproduce and distribute my dissertation, in whole or in part in print, electronic or other medium. I retain the right to use this content in whole or part in future works (such as articles or books).

Abstract

The living standards of elderly people are uplifted through developing assistive robots who are capable of supporting their daily activities by possessing the competency to provide companionship to human beings. Human activities are frequently related to navigational tasks and human tend to use descriptions which include natural language phrases and the terms which describe the distance related uncertainties such as little, large, near, far, small, close to describe about spatial information. Therefore assistive robots should be capable of analyzing and understanding descriptions which include natural language phrases. The best and foremost navigation skills of a robot are represented with the competency of virtual imagination related to an unknown environment. Subsequently the quality of virtual imagination of the robot should be improved with the experiences as human beings. The quality of understanding the user appropriately, efficiently and effectively plays a vital role in order to expand their knowledge as well as the experiences collected from day to day performances and conversations. Accordingly, the robot should contain a memory and an advance knowledge base including the information regarding objects that it experiences in day to day activities. The requirement of a user should be clearly configured with the capability of processing data in order to grasp the relationships among attributes of objects. Obviously, a robot should possess the competency to interpret spatial information in the mode of uncertain terms. Significantly the robot should be capable enough to enhance the knowledge through effective communication with the user.

This research proposes a procedure to understand spatial information in a description with the uncertain terms and creates a conceptual map in a robot memory which can be linked with spatial cognitive map for purposeful, effective and human friendly navigation task. The proposed method is consisted with creation of cognitive object maps and cognitive spatial maps. Further, both maps are created based on information conveyed through interactive conversations between the user, robot and the vocal descriptions. The conceptual maps are created by amalgamating the spatial and object cognitive maps. Moreover, the conceptual map also can be updated using the conversations occurred in the interactions among robot and the user. Furthermore, this research proposes a procedure to enhance the capability of virtual imagination of a service robot while understanding the information regarding the uncertainties of an object size with the aid of artificial neural network. In addition to that gesture command identification method and vocal navigation command identification method are also implemented. Moreover, navigation commands are categorized and studied for the unique attributes such as uncertainty, incompleteness, inconsistency and unpredictability to improve human robot interaction.

The proposed method is validated by the experiments using MI Rob platform (Version 2.0). Further, a software platform was introduced by integrating the implementation of proposed methods. Software platform is consisted of processing spatial maps for room boundary establishment to object identification considering spatial information acquired through descriptions and conversations. System generated data was compared with data derived from human studies and analyzed using statistical methods in order to validate system accuracy. The proposed system can be used to enhance the human-robot interactions and to perform navigational tasks more effectively and purposefully in a previously unknown environment.

Keywords-Virtual Maps, Human-Robot Interaction, Conceptual Maps

DEDICATION

To my beloved parents

ACKNOWLEDGMENTS

I would like to express my deepest appreciation to my supervisors Dr. A. G. B. P. Jayasekara and Dr D. P. Chandima who convincingly conveyed the best attitude on behalf of my research and progress. Their guidance and persistence showed the path of success in regards to this dissertation. Moreover I would like to express my sincere gratitude to the panelists Prof. Nalin Wickckramarachchi and Prof. Ruwan Gopura for the valuable comments provided throughout the years.

I am extremely grateful to my colleagues Viraj Muthugala, chapa sirithunge ,Sahan priyanayana, Baghya samarakoon, Sachi Natasha for the indispensable suggestions provided to complete the thesis.

My heartfelt thanks to parents for their love and continuous assistance given to make this dissertation a success.

Finally, special thanks goes to my dearest friends Sandaruwan Bassnayaka, S.T. Pahattuge, K.D.M. Jayawardhana, T.M. Senarath, B.L.P.M. Balasooriya and Aruna Buddhika for being supportive to complete my thesis successfully.

This work was supported by the University of Moratuwa Senate Research Grant SRC/CAP/17/03 and SRC/LT/2018/20. Furthermore, some of the conference publications originated from this thesis were partially supported by travel grants awarded by IEEE Systems, Man, and Cybernetics Society.
